20 **Abstract**

21 Large Language Models (LLMs), being text-based, are ideal types of artificial intelligence to
22 consider the complexities of palaeontological taxonomy because palaeontology depends on
23 published textual descriptions as the primary, authoritative record of a taxon. This paper
24 describes (1) the preparation of palynological (the study of organic-walled microfossils)
25 taxonomic text contained within the >4500 genera of the Jansonius and Hills
26 palaeopalynological catalogue (JHC) for an LLM-augmented taxonomy system (LATS), (2) the
27 efficiency and accuracy of the LATS, and (3) examples of possible further uses of the LATS
28 beyond aids to identification. The conversion of the JHC into a LATS is typical of the challenges
29 of making so called ‘long tail’ data suitable for AI development and can involve considerable
30 manual checking. Principles of development include (1) ‘inclusion’, that is, making sure that the
31 LATS as far as possible includes rather than excludes candidate genera; (2) the principle of
32 ‘assistance’ rather than supplantation so that the LATS is intended as an aid to taxonomy, not a
33 replacement for a human taxonomist; and (3) the principle of ‘non-intervention’ whereby no

34 alterations to original authoritative genus descriptions or diagnoses are applied. Training for the
35 dataset involved 500 Question/Answer pairs generated for the JHC by specialists, as well as
36 additional synthetic QA pairs which, combined, were used to supervised-fine tune the LLM.

37 The LATS functions through Retrieval Augmented Generation and returns candidate genera with
38 statistical measures of match against the prompt(s). Access to full descriptions of genera
39 extracted from the JHC and to scans of the original catalogue cards allow the taxonomist to use
40 their own judgment in final identification. The LATS produces generally good results but there
41 are two types of limitations or shortcomings: those that emanate from the JHC (and
42 palaeopalynological taxonomy itself), and those that emanate from the working of the LATS.
43 Limitations due to the JHC include (1) poor potential for discrimination between some genera
44 because of poor original descriptions which have not been subsequently emended, (2)
45 numerous candidate genus names that may be synonyms, and (3) invalid candidate genera, i.e.
46 that were illegitimately published. Limitations that emanate from the working of the LATS
47 include evidence of bias against finely described genera.

48 As well as providing a LATS to aid a palynologist through the stages of identification, the
49 information and ‘understanding’ that the underlying system has of a large area of
50 palaeopalynological taxonomy means that the system could be put to more general uses for
51 example in the identification of genus names that are likely synonyms, and investigation of the
52 distribution of genera (or taxa) in ‘morphological space’.

53 The development of the LATS described here has implications for other palaeontological groups
54 in terms of the text basis of their taxonomy (for example variable quality of descriptions and
55 inconsistency in terminology), and their suitability for development of other LLM-assisted
56 taxonomic aids.

57 **Introduction**

58 Palaeontological and palaeopalynological taxonomy aims to classify fossil organisms, provide
59 stable names for unambiguous communication, and organize diversity by placing fossils into
60 hierarchical groups (species, genera, families, etc.) that reflect evolutionary relationships. The
61 determination of a specimen to a taxon requires reference to literature, type specimens,
62 illustrations and photographs.

63 Early taxonomic keys (e.g. Lamarck 1778) were used as aids to determination and used
64 dichotomous processes that allow the user to choose between opposing pairs of morphological
65 characters; and keys continue to be used for example in botany and zoology (e.g. ZoologyTalks:
66 <https://www.zoologytalks.com/types-of-taxonomic-keys/>). Text-based palynological keys have
67 been published in archaeological studies (e.g. Hubbard 1992), and in palaeopalynology (e.g.
68 Steemans and Wellman 2018), and several modern pollen identification keys exist: for example,
69 Das et al. (2025) constructed a taxonomic key for Papilioideae (Fabaceae) from Northeast
70 India. The use of artificial intelligence in identification keys is rare (Yu et al. 2024), an exception
71 being Liu et al. (1994) who constructed a dual-step identification tool with a Knowledge-Based
72 System (KBS) and an image analysis subsystem, which extracted graphic information from
73 foraminifera chambers and suture images in addition to previous shape analysis based on
74 Fourier analysis and edge detection.

75 Various forms of artificial intelligence have also been used to aid palynomorph identification
76 using image recognition (e.g. Zhang et al. 2004, Rodriguez-Damian et al. 2006, Mander et al.
77 2013, Kong et al. 2016, Niu et al. 2024, von Allmen et al. 2024) based on learning from very large
78 numbers of high-resolution images of specimens whose taxonomic status were validated by
79 experts, though not by direct reference to authoritative text-based diagnoses or descriptions of
80 taxa. Thus, the expert validations are placed between the user and the first-principle taxonomic
81 information. Though they may supply accurate determinations within that framework, their

82 taxonomic decisions are not visible to the user, and their methods do not offer pedagogic value
83 or insight into processes of taxonomic decision-making.

84 Large Language Models (LLMs), being text-based, are ideal types of artificial intelligence to
85 consider the complexities of palaeontological taxonomy because palaeontology depends on
86 published textual descriptions as the primary, authoritative record of a taxon (ICZN 1999;
87 Turland et al. 2025). An LLM-augmented taxonomic key was developed for a small dataset of
88 around 70 spore species from the Carboniferous-Permian of the Arabian Plate (Stephenson et
89 al. 2025) as a pilot project. This allowed users to make choices amongst a fixed set of options
90 and then allowed free text prompts to refine the search. Because of the small size and limited
91 applicability of the system, it was not released publicly.

92 Considering these developments, we investigated the possibility of constructing an LLM based
93 system that would respond to simple descriptive prompts rather than requiring a series of
94 dichotomous or polytomous choices. LLMs ‘learn’ from extensive text datasets, including
95 books, articles, and websites which helps them recognize patterns in language, grammar,
96 meaning, and context (e.g. Patil & Gudivada 2024). Transformers enable models to weight
97 different words and phrases based on their relationships within a sentence. Text is broken down
98 into smaller units (tokens), which the model processes to predict the most likely next words in a
99 sentence or generate full responses. LLMs generate text by predicting the most statistically
100 probable sequence of words based on their training (Bender and Koller 2020). When applied to
101 palynological identification scenarios, LLMs are also expected to bring several distinct
102 advantages:

103 1. Unlike many areas of modern biology that can rely on genetics, living specimens, or
104 high-resolution imaging, palaeontology depends on published textual descriptions as
105 the primary, authoritative record of a taxon (e.g. Gravendyck et al. 2021). Under the rules
106 of zoological and botanical nomenclature (ICZN 1999; Turland et al. 2025), a species

107 becomes valid only when it is described in text. Text provides the diagnosis (what makes
108 the taxon unique), the description (its full morphological characterisation), the type
109 designation (holotype, lectotype, etc.), and the comparisons with similar taxa. All these
110 elements must be written, published, and permanent. Even high-quality plates or
111 photographs cannot capture subtle morphological distinctions and variability, describe
112 internal structures not visible externally, or explain reasoning behind taxonomic
113 decisions. In this sense, text provides the conceptual framework that the images
114 support. Text allows reproducibility and comparison because future researchers must
115 be able to compare new specimens to the original description, evaluate whether a fossil
116 belongs to an existing species, and identify synonyms. Large Language Models (LLMs),
117 being text-based, are therefore ideal types of artificial intelligence to consider the
118 complexities of palaeontological taxonomy because palaeontology depends on
119 published textual descriptions as the primary, authoritative record of a taxon.

120 2. Human-like interaction and interpretability: unlike image-based identification apps for
121 botany (for example those on an iPhone such as PictureThis®) which function without
122 human interaction in decision making (i.e. they are black-boxes), LLMs can show
123 reasoning and generate human-readable explanations and responses, enabling more
124 interpretation of classification decisions. It also allows the interpretation of
125 morphological details that may not be discerned from a photograph. This capability
126 supports greater transparency and user trust in AI-assisted identification systems.

127 3. LLMs exhibit strong language comprehension abilities, allowing them to capture subtle
128 semantic distinctions (e.g. Rogers et al. 2021). This is particularly beneficial in
129 identification tasks where subtle differentiation between similar taxa is required,
130 thereby addressing persistent challenges such as ambiguous terminology, short or
131 inadequate descriptions, or continuous variability between taxa.

132 4. LLMs possess broad world knowledge, including foundational understanding in many
133 scientific domains allowing extraneous knowledge to be brought into taxonomic
134 decision making, for example translation of Latin-based terminology.

135 The purpose of this paper is to describe the preparation of palynological taxonomic text for an
136 LLM-augmented taxonomy system (LATS) of more than 4500 genera, the efficiency and
137 accuracy of the LATS, and potential further uses of the LATS beyond identification. The LATS is
138 intended for open and free use for all scientists and provides a guide to determination rather
139 than acting as an ultimate arbiter of genus determination.

140 Preparation of the data

141 Background

142 Much data generated by geoscientists is still not accessible to other geoscientists or to artificial
143 intelligence tools (Stephenson et al. 2020). This is a problem for geoscience and other
144 observational sciences which often rely on mixed qualitative and quantitative data that is part of
145 the so-called ‘longtail’ (e.g. Sinha et al. 2013) – the unstructured and heterogeneous datasets of
146 geological surveys, university research groups, and individual scientists. Palynological
147 taxonomic datasets are often similar: they may have been collected and compiled from the
148 peer-reviewed literature, developed separately from the peer-reviewed literature, or exist only as
149 separate records (diagnoses/descriptions) in the peer-reviewed literature, often behind a
150 paywall. This often hinders palynological taxonomic study and determination of species and
151 genera, because of the size of datasets, their heterogeneity in terms of language, terminology,
152 precision and comprehensibility - and in the case of paywalled information - their
153 inaccessibility.

154 An example of a large openly available palaeopalynological database is the Jansonius and Hills
155 Catalogue (JHC; 1976 and subsequent updates) of fossil spore and pollen genera. The JHC was
156 created as a series of physical cards - originally one card per genus – and contains more than

157 4500 spore (fungi, plants and algae) and pollen genera from the Phanerozoic Eon spanning the
158 last 540 million years. This database was created by Calgary palynologists J. Jansonius and L. V.
159 Hills and provides original authorial (i.e., sourced from the peer-reviewed literature)
160 descriptions and diagnoses for these genera, details of the source publications and authors,
161 descriptions of genus type species, and often subsequent genus descriptions, including formal
162 emendations. Taken as a whole, the catalogue is a useful resource which has no other
163 equivalent in palaeopalynology. The physical cards of the JHC were scanned into the form of a
164 PDF in the early 2000s, and are freely accessible online at the Calgary University Library website
165 (https://openlibrary.org/books/OL22388791M/Genera_file_of_fossil_spores_and_pollen).
166 Permission was granted from the Jansonius family and the University of Calgary to proceed with
167 the development. The first 78 pages of the PDF consists of an introduction, genus lists,
168 corrigenda and addenda, and p. 79-5676 are the genera files.
169 The AI assisted key of Stephenson et al. (2025) was developed for a small dataset, and 'chain of
170 thought' logical steps were embedded in the system through structuring of the learning material
171 (for example in providing sequenced choice stages linked to hierarchical aspects of taxonomy).
172 The approach to the development of a LATS for JHC was different because of the difficulties of
173 pre-structuring such a large dataset of very heterogeneous palynomorph types (fungal spores,
174 vascular plant spores, angiosperm and gymnosperm pollen, algal and other spores). For this
175 LATS, the Retrieval-Augmented Generation (RAG) technique was adapted to search for the best
176 matches based on users' descriptions, incorporating, if necessary, iterative sequences of
177 prompts. (Lewis et al. 2020)
178 **Guiding principles during preparations of materials**
179 A number of principles were decided on before development, these included inclusion,
180 assistance, and non-intervention.

181 *Principle of inclusion*
182 Any taxonomic key or identification system attempts to narrow down possible ‘candidates’
183 using information provided by the user (the user’s ‘prompts’). Many early guides used
184 dichotomous keys, which are classification tools that allow the user to choose between
185 opposing pairs of morphological characters necessitating the rejection of groups of taxa at each
186 point of choice (e.g. Lamarck 1778). In the present system which uses a Retrieval,
187 Augmentation, and Generation (RAG) method, the quality of the initial prompt - in terms of
188 accuracy and detail -determines the numbers of candidate taxa, and the quality of the match
189 between the prompt (the description of the observed specimen) and the candidates. However,
190 both methods of input potentially exclude candidate taxa, if a mistake on the part of the user is
191 made early on. Thus, the system is designed as much as possible to allow a user to backtrack if
192 necessary, and to include rather than exclude candidate taxa; in other words, if in doubt, the
193 system includes rather than excludes candidate genera.

194 This principle is extended to taxa that are invalid (not published legally in line with ICBN rules).
195 Many of the genera in JHC are invalid in that for example, a holotype was not designated. The
196 system however includes any relevant invalid genera (identified by Jansonius and Hills or
197 identified subsequently) within its candidate lists following a prompt. The genus is noted as
198 invalid but is included for completeness. It is sometimes the case that invalid genera are later
199 validated (for example by designating a holotype) because they are considered useful. Thus, in
200 keeping with JHC, the system is inclusive in the spirit of helping to keep taxonomy transparent.

201 *Principle of assistance*
202 The LATS is intended as an aid to taxonomy, not a replacement for a human taxonomist. The
203 principle followed in the design is that the LATS provides relevant information to allow the
204 taxonomist to make an informed determination. The use of the LATS encourages transparency in
205 that the system provides information at every step; and through regular use, has pedagogic
206 value in that it illustrates how palynological taxonomy proceeds. This contrasts with image

207 recognition systems that essentially recognise visual patterns and do not consider the
208 authoritative text.

209 *Principle of non-intervention*

210 The database developed by Jansonius and Hills is unaltered in the LATS. Although it is possible
211 that improvements to diagnoses (for example making them clearer or more precise) would
212 improve the LATS's discrimination capability, this would involve decisions made by the creators
213 of the LATS, which would be interventionist. Further use of the LATS and the system that
214 underlies it could bring about improvement and rationalisations in palaeopalynological
215 taxonomy (for example by identifying possible synonyms, see later section) but this would have
216 to be done as a community, perhaps at some future date.

217 **Challenges**

218 The first challenge is the quality and non-standard format of the PDF resulting from the scan of
219 the original JHC cards. The text was originally manually typed onto cards in the 1970s and 80s
220 and some of the typed letters are not clear which causes problems for machine recognition. An
221 example is that the machine does not distinguish always between the typed letter "O" and
222 number "0", with the result that the names of genera and their characteristics are sometimes
223 obscured. Similar mistakes occur with recognition of line breaks, non-standard symbols and
224 letters, or letters with umlauts, for example. Correction of these mistakes can be a long,
225 laborious process involving manual checking of OCR (Optical Character Recognition) results.

226 A second issue is that the quality of original descriptions and diagnoses of genera transferred
227 from the literature into JHC is very variable. There are some excellent comprehensive
228 descriptions and diagnoses of genera erected in the later years of the rapid expansion of
229 palaeopalynology in the 1960s and 1970s, particularly when the science was being taken up by
230 the oil industry. However, many early genus descriptions and diagnoses are very short and
231 sketchy, partly because at the time of their composition, palynology was a young science, and
232 few other genera had been recognised and low levels of detail in descriptions and diagnoses

233 were the norm. Jansonius and Hills also correctly recognised that some genera have been
234 invalidly published, so some names appearing in the JHC are superfluous. Jansonius and Hills
235 often dealt with descriptions and diagnoses in foreign languages by translating them (many are
236 translated from Russian). The variability in diagnosis/description leads to other difficulties of
237 bias and an inability of the system to distinguish genera. This is discussed in a later section.

238 Inconsistent use of terminology is a third issue. This inconsistency occurs in several forms, for
239 example synonyms for the same ornament element type (verrucae/warts; see e.g. Punt et al.
240 2007), or more commonly multiple slightly different versions of descriptive terms (spines or
241 spinae; bacula or baculae). Palynological terminology has also developed near parallel systems
242 (e.g. exoexine/intexine, nexine/sexine; cavate/camerata; e.g. Punt et al. 2007) often due to
243 different usage in the different international ‘schools’ of palynology, and different terminology
244 developed for different time periods (e.g. the Palaeozoic and Cenozoic; Stephenson 2016).

245 Elements of LLM training can alleviate these problems through the creation of ‘question-and-
246 answer pairs’ because they help the LLM to learn the meanings of terms, their interchangeability
247 and their variability, and how to generate relevant, structured, and context-aware responses
248 (e.g. Wei et al. 2022). For the JHC, two kinds of question-and-answer pairs were developed. The
249 first were structured QA pairs directly anchored in the original diagnosis or description as
250 supplied in the JHC; in other words, the answers to the questions can be found directly within
251 the text. A set of Q&A pairs for the spore genus *Bellisporites* is shown in Fig. 1. Most questions are
252 simple: ‘Question; What kind of germination mark does *Bellisporites* have?’, ‘Answer; *Bellisporites*
253 has a trilete mark’; and the answers can be found directly in the corresponding card/record (Fig.
254 1). QA pairs must also include similarly anchored compound questions (requiring integration of
255 multiple information), and counterintuitive questions (testing the model’s error-correction
256 ability, e.g. ‘Is *Bellisporites* monolete?’). The simple, compound and counterintuitive QA pairs are
257 used to ‘supervised fine tune’ the model to expand the word lists for the genera.

Q&A for *Bellisporites*

Q	A
What kind of germination mark does <i>Bellisporites</i> have?	<i>Bellisporites</i> is trilete
What kind of amb does <i>Bellisporites</i> have?	<i>Bellisporites</i> is triangular
What shape are the sides (between the apices) in <i>Bellisporites</i> ?	The sides (between the apices) in <i>Bellisporites</i> are slightly concave
What kind of ornament does <i>Bellisporites</i> have?	<i>Bellisporites</i> is smooth or weakly infrapunctate
Does <i>Bellisporites</i> have a zona or a flange?	Yes <i>Bellisporites</i> has a zona or a flange
How wide is the zona or flange in <i>Bellisporites</i> ?	The width of the zona or flange in <i>Bellisporites</i> is about half the spore radius
Does the zona or flange have any structure or features in <i>Bellisporites</i> ?	The flange of <i>Bellisporites</i> is unstructured but has indentations along the edge of the zona or flange
How long are the leasureae (rays of the Y mark) in <i>Bellisporites</i> ?	In <i>Bellisporites</i> the leasureae (rays of the Y mark) extend to the flange
Do the leasureae in <i>Bellisporites</i> have any structure?	The leasureae in <i>Bellisporites</i> have thin raised lips

246

BELLISPORITES Artūz 1957
İstanbul Univ., Fen Fak., seri B., cilt 22, sayı 4, p. 254.

Type species: *Bellisporites bellus* Art., l.c., p. 255, pl. 7, fig. 49

Diagnosis: "Trilete iso- and microspores with triangular amb; sides slightly concave, angles rounded; spore surface usually smooth, often also weakly infrapunctate; along the (secondary) sides there are numerous small, shallow, spine radius; flange without structure, having numerous more or less irregular indentations along the periphery; rays Y-shaped, long and straight; three radial thickenings are located on the surface; equatorial border narrow, of uniform, thickness."

Diagnosis given by Sullivan 1964 (Palaeontology, v. 7, pt. 3, p. 37a): Spores radial, trilete, lenticular in side view; amb triangular, sides straight or concave; trilete rays prominent, tecta long and straight; three radial thickenings are located on the surface; equatorial border narrow, of uniform, thickness.

Type species: 34-45_u (holotype 36_u), flange 5-7_u wide, with crenate outline and secondary folds. Westphalian A, Zengüldeş area, Turkey.

Monospecific, no differential diagnosis in 1957.

JHC card for *Bellisporites*

258

259 Fig. 1. A series of QA pairs for the spore genus *Bellisporites*

260 The second type of QA pairs is known as 'incorporate' (e.g. Ouyang et al. 2022); these cover
261 areas of palaeopalynology, for example, basic principles and terminology outside the
262 immediate learning materials, so outside the original diagnosis or description as supplied in
263 JHC. They include questions like 'What are the characteristics of zonate spores?' and 'Describe
264 all the features of monolete spores.' The incorporate QA pairs are similarly used to supervised-
265 fine tune (SFT) the LLM in the broader knowledge of palynology, resulting in improved
266 understanding and interpretation of taxonomic terminology in the genera descriptions.

267 The embedding model was trained as follows: 1894 more incorporate QA pairs were generated
268 based on the 206 incorporate QA pairs provided by specialists with the GPT-5 model. These
269 generated QA pairs did not alter the meanings in the original question and answer pair but
270 changed the order and manner of the word usage. These QA pairs were then proofread by
271 specialists to make sure that no mistakes were made. For genus-related QA pairs, the LLM
272 learned the patterns of QA pairs created by specialists and generated 18 QA pairs in total for
273 each genus. (6 simple QA pairs, 6 compound QA pairs and 6 counterintuitive QA pairs) Some
274 genera in the JHC have no diagnosis (e.g. *nomina nuda*) and were removed so 69299 QA pairs
275 were used for training.

276 Among these 2100 incorporate and 69299 genus-related QA pairs, 1000 QA pairs were randomly
277 selected as the test set and Mean Reciprocal Rank (MRR) and Recall were used as evaluation
278 criteria. MRR indicates the quality of the position of the first relevant result in the retrieval
279 ranking under a single query, which can be considered as a measure of the accuracy of the
280 embedding model in semantic understanding. Recall, usually Top-K recall, measures the
281 proportion of all relevant results that are retrieved and included in the Top-K ranking under a
282 single query.

Criteria	MRR		Recall	
	Top-K	Before SFT	After SFT	Before SFT
Top 1	0.514	0.901	0.514	0.901
Top 10	0.625	0.935	0.846	0.984
Top 100	0.630	0.936	0.943	0.994

283 Table 1. embedding model performance on semantics of palynological knowledge and
284 professional terminology before and after supervised fine tuning. MRR = Mean Reciprocal Rank;
285 SFT = Supervised Fine Tuning.

286 Based on the results (Table 1), it is clear that the embedding model better understands the
287 semantics of palynological knowledge and professional terminologies after supervised fine
288 tuning. This improves the evaluation of semantic similarities between user input and diagnosis.

289 **Model construction**

290 There are three major steps in the LATS: (1) understand users' input (prompt) and provide
291 reasonable matches; (2) provide a ranked list of candidates based on the calculated similarity
292 scores between users' prompt and genera diagnoses; and (3) provide tips to improve users'
293 prompts and a suggested refined query or prompt (Fig. 2.). Note that reasonable matches in

294 Step 1 are generated purely with the LLM and can be minorly varied given identical input. While
295 the list of candidates in Step 2 is provided based on statistical analysis, comparing the user
296 input only with diagnosis at genus level, the LATS would first transfer user input to vectors based
297 on the embedding model, then use cosine similarity to calculate the semantic similarity. (Salton
298 et al. 1975, Deerwester et al. 1990)

299

$$\cos\theta = \frac{\vec{A} \cdot \vec{B}}{\|\vec{A}\| \times \|\vec{B}\|}$$

300 where the numerator is the dot product of vectors \vec{A} and \vec{B} ; the denominator is the product of
301 the L2 norms of vectors \vec{A} and \vec{B} . Namely, the candidate list would remain the same given
302 identical user input. A threshold is then set to include as many similar taxa as possible, rather
303 than eliminating possibilities, and users can choose to show the top 5, top 10, or top 20 genera
304 only. At this point an ‘approximate string matching’ or ‘fuzzy’ search is also possible (Ukkonen
305 1985, Bast and Celikik 2013). This is a search method that finds results not identical to the
306 query but similar or closely related to it. It tolerates typos, misspellings, missing/extra
307 characters, or minor formatting differences—unlike exact search, which only returns perfect
308 matches.

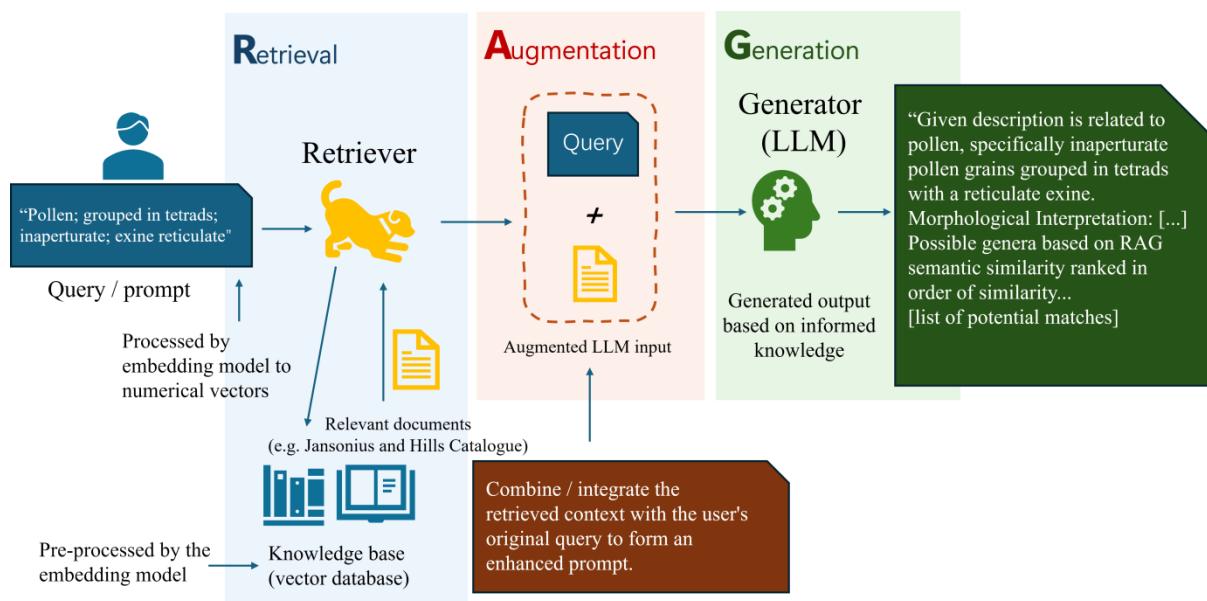

309 The LATS is built with the GeoGPT 72B model, which is trained on an open-source LLM Qwen-
310 72B from Alibaba Group (Yang et al. 2025). The training process for the GeoGPT models consists
311 of three key stages.:

312 1. Continual Pre-training (CPT) : The continual pre-training stage utilizes a variety of
313 datasets, including open access papers/books, and geoscience-related materials from
314 Wikipedia and Common Crawl that grant rights for non-commercial LLM modeling
315 training and model output sharing. This extensive corpus is used to ensure a solid
316 foundation in geoscience literature (Gururangan et al. 2020).

317 2. Multi-stage Supervised Fine-tuning (MSFT): The fine-tuning process is divided into three
 318 stages to refine the model's performance, using curated open-source QA pairs, the
 319 filtered Tulu-v3 dataset, geoscience-related QA data and long-context data. (Ouyang et
 320 al. 2022)

321 3. Direct Preference Optimization (DPO): The final stage, direct preference optimization,
 322 involves refining the model based on prompts paired with preferred answers. This
 323 ensures that the model's responses align more closely with user expectations and
 324 preferences. (Rafailov et al. 2023)

325 These processes ensure that the GeoGPT model is trained on a wide range of geoscience data,
 326 fine-tuned for specific tasks, and optimized for user preferences. All the data used for training
 327 comes from open-access publications with permission to train non-commercial LLM and share
 328 model output. (GeoGPT User Manual 2026).

329

330 Fig. 2. RAG workflow for LATS.

331 The essence of the embedding model is to convert discrete and unstructured text into fixed-
 332 dimensional continuous dense vectors (embedding vectors), enabling machines to achieve
 333 semantic-level understanding, matching, and interaction through vector similarity calculations.

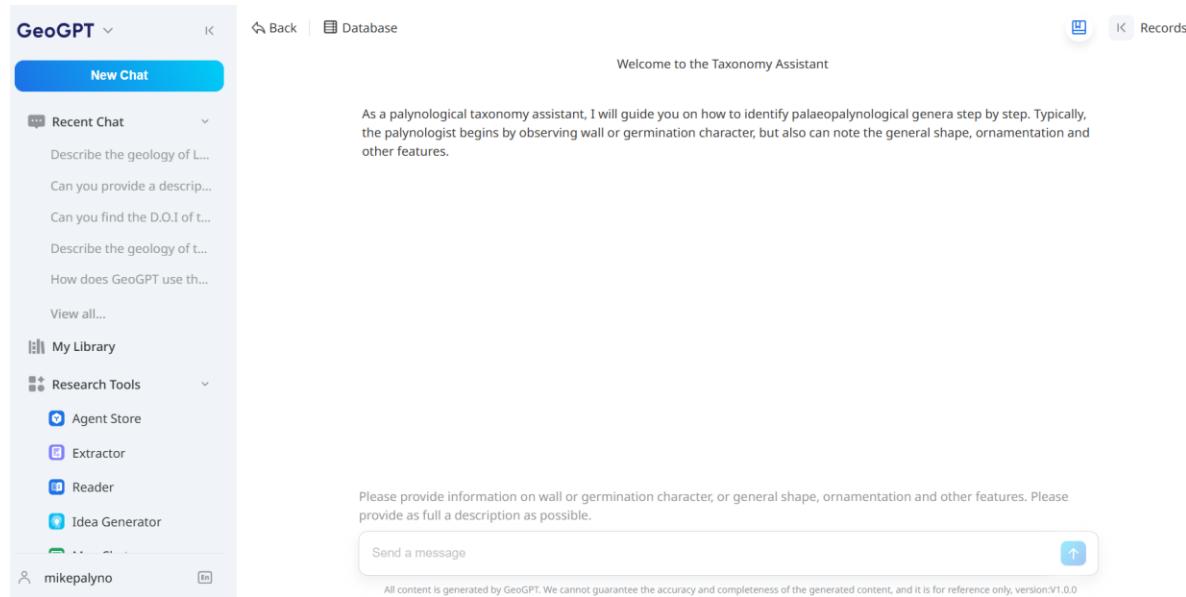

334 (Reimers and Gurevych, 2019). The embedding model for this LATS is the BAAI General
335 Embedding large v1.5 (BGE-large-en v1.5) (Zhang et al. 2023, Chen et al. 2024). The BGE model
336 is a universal open-source embedding model that is commonly used in the open-source
337 community. The model adopts RetroMAE (Retrieval-oriented Language Models Via Masked
338 Auto-Encoder) pre-training technology and the large-scale contrastive learning training strategy,
339 and has been specially optimized for the problem of similarity distribution. (Xiao et al. 2022) In
340 version 1.5, it significantly improved the rationality of the similarity score distribution and
341 improved the ability to retrieve candidate genera. In the future development plan, the
342 embedding model will be trained using the QA pairs provided by palynological experts and
343 explanations of professional terms, enabling the LATS to possess palynological expertise,
344 thereby better understanding the user input and providing better matching of candidate genera.

345 Finally, a measure was taken to determine whether the prompt is related to spores, pollen, or
346 other palynomorphs (e.g. dinoflagellate cysts, chitinozoans, acritarchs). If irrelevant, the LATS
347 would clearly state that the description is not related to palynology and suggest how to describe
348 morphological features relevant to spores, pollen, or other palynomorphs (e.g. shape, size,
349 ornamentation, aperture type, etc.). Then immediately end the response. If there were multiple
350 rounds of input, the LATS would consider all user inputs and generate matching results based
351 on all historical inputs. Additionally, users are allowed to edit previous input and re-generate
352 answers from any historical round. After the re-generation, the system will retain all outputs
353 from previous rounds but clear the subsequent generation of the edited round and start
354 generating again based on the new input. Meanwhile, the system also provides a history record
355 module, through which users can access the historical records along with the corresponding
356 generated output.

357 **Operation of the system**

358 The LATS has a simple interface with a box for the user to type in a description as a prompt (Fig.

359 2).

360

361 *Fig. 3. Box for prompt*

362 If a description such as 'Pollen; grouped in tetrads; inaperturate; exine reticulate' is entered, the

363 LATS provides first a morphological interpretation of the user's description (Fig. 3). The purpose

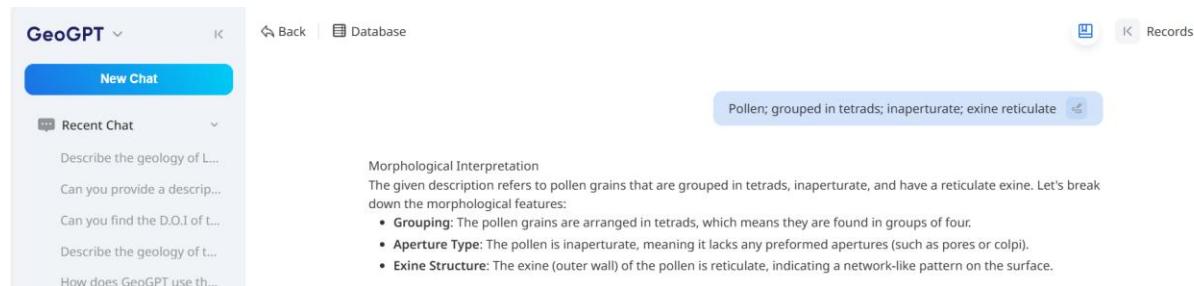

364 of this section is for the user to check that the LATS understands the prompt, for example the

365 prompt mentions 'grouped in tetrads' and the LATS states that 'the pollen grains are arranged in

366 tetrads which means they are found in groups of four'; similarly, the LATS confirms the meaning

367 of 'inaperturate'. At this point, if the LATS does not understand the prompt, it will be clear to the

368 user who can backtrack and enter a slightly different prompt, perhaps with alternative terms.

369

370 *Fig. 4. Morphological interpretation of the user's description*

371 Following this stage the LATS produces the best five matches for the genera (Fig. 4) in relation to
372 the prompt description. These are not in order of level of fit. The LATS provides the name of the
373 candidate genus, details of the genus and the rationale for the selection.

Matching Reference Records

Based on the described features, the following reference records are the most likely matches:

- 1. INAPERTUROTETRADITES**
 - Details: Inaperturate pollen grains, grouped in tetrads. Non-aperturate tetraedral pollen tetrads with reticulate sculpture.
 - Rationale for selection: This record perfectly matches all the described features: inaperturate, grouped in tetrads, and reticulate exine.
- 2. RETITETRADITES_A**
 - Details: Pollen tetrads with reticulate sculpturing.
 - Rationale for selection: While this record does not explicitly mention inaperturateness, it describes pollen tetrads with reticulate sculpturing, which aligns well with the given description.
- 3. CATALPOLLIS**
 - Details: Nonaperturate tetrahedral pollen tetrads with areolate-reticulate surface. Reticulum resides in columella-layer.
 - Rationale for selection: This record describes nonaperturate tetrads with a reticulate surface, closely matching the given description.
- 4. DROSERAPITES**
 - Details: Grains tetrad. Individual grains inaperturate the mixed with dense clavate and baculate processes; sexine reticulate.

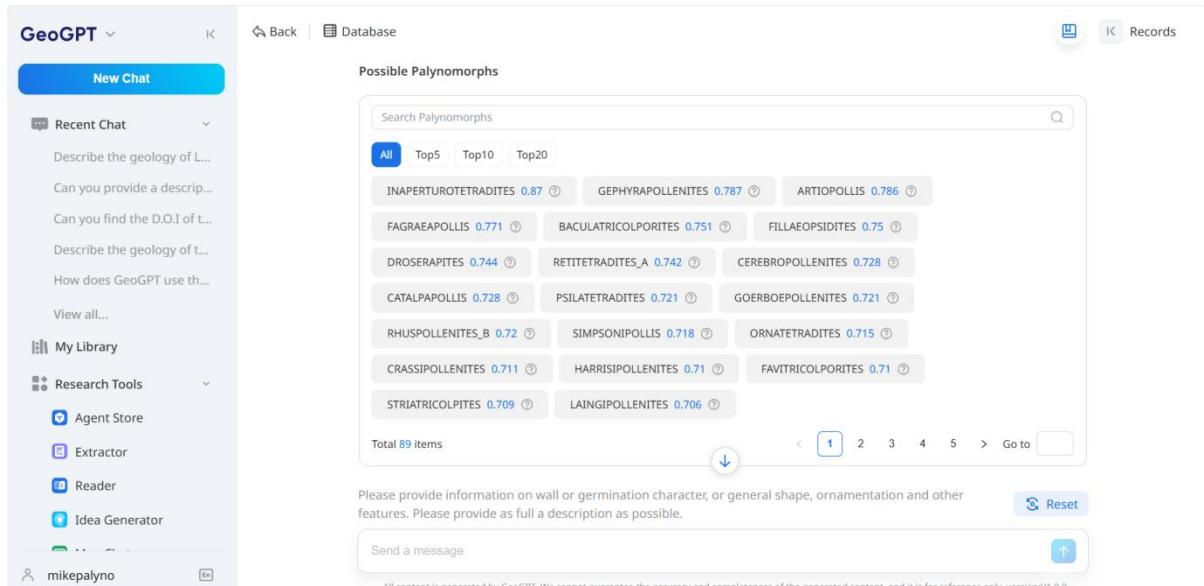

Please provide information on wall or germination character, or general shape, ornamentation and other features. Please provide as full a description as possible.

374

375 *Fig. 5. Best five matches*

376 Below this, is a broader assessment of semantic similarity (Fig. 5), with candidate taxa ranked in
377 order of statistical similarity. This assessment provides the wider context of possible genera. At
378 either this stage or the previous stage the description/diagnoses of the candidate taxa can be
379 consulted, and the original scans of JHC can also be consulted through clicking the 'Database'
380 icon or the genus candidate names. Many JHC cards contain simple line drawings of the main
381 features of genera.

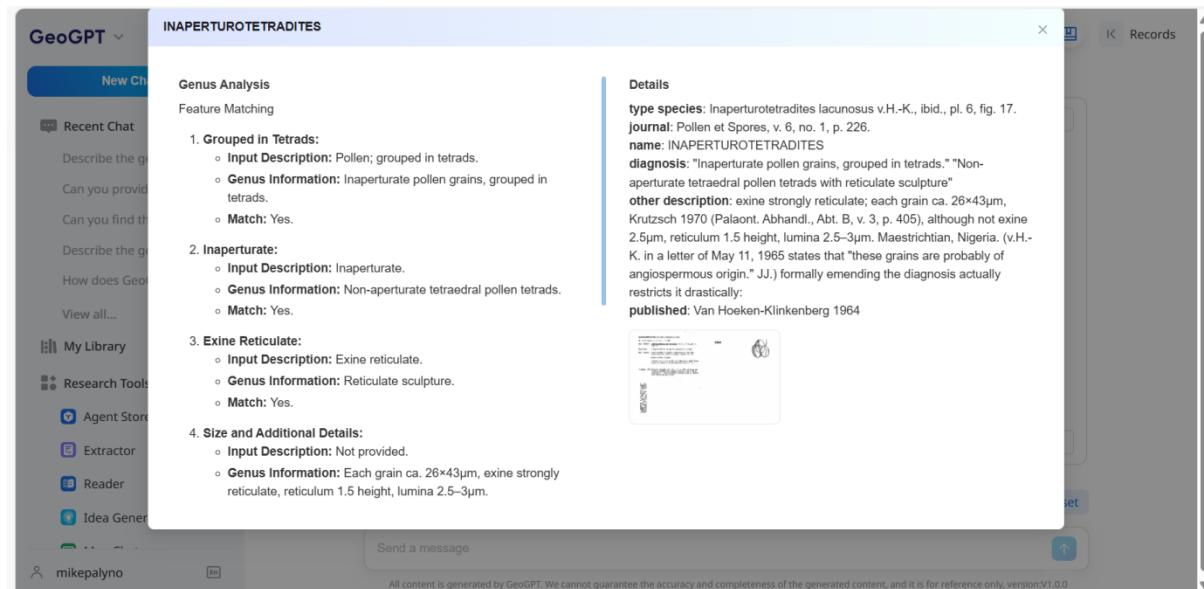

382

383 *Fig. 6. Broader assessment of semantic similarity*

384 For a detailed rationale for the match as well as areas where there is a mismatch, an
385 assessment is also available for each candidate genus (Fig. 6)

386

387

388 *Fig. 7. Detailed rationale including reasons for match and mismatch for each candidate genus*

389 The LATS also provides tips to improve the prompt and a suggested refined query or prompt (Fig.
390 7).

The screenshot shows the GeoGPT interface. On the left, there's a sidebar with 'Recent Chat' (describing the geology of L...), 'My Library' (empty), and 'Research Tools' (Agent Store, Extractor, Reader, Idea Generator, Map Chat, Map Generator). The main area shows a user query: 'Describe the geology of L...'. Below it, a list of pollen genera with their scores: CRAASSPOLLINITES 0.711, HARRISIPOLLINITES 0.71, FAVITRICOLPORITES 0.71, STRATRICOLPITES 0.709, and LANGPOLLINITES 0.706. A message box says: 'query is indeed related to palynology, as it describes specific features of pollen grains. To refine the query for more accurate matching and identification, we can focus on key palynological features such as size, shape, aperture type, surface ornamentation, and exine structure.' Below this are 'Suggestions to Improve the Query' with numbered points: 1. Size (in microns), 2. Shape, 3. Aperture Type, 4. Surface Ornamentation, and 5. Exine Structure. A 'Suggested Refined Query' box contains: 'Pollen; grouped in tetrads; inaperturate; exine reticulate; size 20-30 µm; spherical; exine layered.' A note says: 'This refined query includes all the key palynological features, making it easier to match with relevant information and databases.' At the bottom, there's a message input field with 'Send a message' and a 'Reset' button.

391

392 *Fig. 8. Tips to improve user's prompt and a suggested refined query or prompt*

393 Limitations of the system

394 There are two types of limitation or shortcoming: those that emanate from JHC itself, and those
395 that emanate from the system.

396 Limitations due to JHC

397 The JHC contains genus names that are (1) poorly described, because they were originally
398 poorly described in the relevant peer-reviewed paper or report, and their descriptions or
399 diagnoses have never been improved, (2) invalid, (3) are described in translations into English
400 from original diagnoses, introducing an element of interpretation on the part of the translator,
401 (4) acknowledged and unacknowledged synonyms, and (5) homonyms. Jansonius and Hill's
402 aims were to document as completely as possible the array of genera that a palaeopalynologist
403 has at his/her disposal. Regular users of the PDF of JHC are aware of these characteristics, and
404 aware that information in JHC is not sufficient to distinguish certain genera - or that certain
405 useful genera are technically invalid. This often means that it is impossible using the
406 information provided to make a satisfactory determination. This is not the fault of JHC, but of the
407 taxonomy of palaeopalynology itself, which grew rapidly from a relatively small database in the

408 early 19th Century to a growing science in 1960s and 70s, particularly as its use in economic
409 biostratigraphy became important (e.g. McGowran 2005). Thus, the LATS does not provide any
410 better levels of discrimination between some genera but simply offers the same potential for
411 determination as study of the JHC. Here a few examples are examined and discussed in detail.

412 *Valid but 'redundant' genera*

413 Amongst the many genera of the JHC are those that are valid but rarely 'used'. This is often the
414 case with genera that have been described early in the growth of palaeopalynology as a
415 discipline. Their diagnosis or description may be rather short often because - to the original
416 describing palynologist - there appeared to be few similar genera to discriminate. An
417 explanation for their low usage maybe that later palaeopalynologists preferred to use genera
418 that seemed more appropriate with more circumscribed morphological variation. Another
419 explanation for this 'redundancy' relates to the siloed expertise of palaeopalynologists in a
420 certain Period (for example the Permian), and a particular group of genera become associated
421 with that system which become habitually used by 'Permian palynologists' even though suitable
422 genera may be available in the Mesozoic (for example the Triassic).

423 An example is the genus *Cingulazonites* Mädler 1964, from the Upper Rhaetian of Germany
424 (Upper Triassic). Its diagnosis (translated from the German) is: '*Trilete miospores, amb*
425 *subcircular to rounded triangular; cingulum present, thinning wedge shaped towards the*
426 *equatorial margin, and grading into a narrow zona; cingulum smooth and structureless, which*
427 *differentiates the genus from Densosporites*' (Mädler 1964). A palaeopalynologist working in a
428 Carboniferous succession observing a spore with '...cingulum present, thinning wedge shaped
429 towards the equatorial margin...' might expect to find the genus *Cingulizonates* (first erected by
430 Dybova & Jachowicz 1957 from the Upper Carboniferous) among the higher-matching LATS
431 candidates but will also find *Cingulazonites* which is never used in the Carboniferous, even
432 though its circumscription is suitable for many spores that might be assigned to *Cingulizonates*.

433 *Invalid genera*

434 As discussed above, the JHC includes genera that are invalid under ICBN rules, as well as
435 genera originally considered invalid but then made valid through, for example, the designation
436 of a holotype by a later author (see e.g. McNeil 2014). All this information, when available in
437 JHC, is also included in the LATS. Thus, a prompt will potentially provide these kinds of genera.
438 Though this could be considered a limitation, the LATS allows the palynologist to see a full range
439 of candidate genera without exclusion. As stated in the principle of ‘assistance’ above, the
440 purpose of the LATS is to assist the palynologist in his/her determination, rather than supplant
441 the palynologist’s role.

442 *Near-synonyms*

443 A related challenge is that as with JHC, the LATS, following a prompt, may return candidates
444 which are very close morphologically. As discussed later in this paper, conceptual
445 ‘morphological space’ appears to be crowded in some areas of palynological taxonomy,
446 particularly where small differences in morphology are considered important for
447 biostratigraphy, for example in the Palaeozoic of the Middle East and the Mesozoic of the North
448 Sea. Thus, prompts with low discriminative potential may supply many, very similar genera. In
449 these, the judgment of to the user is required to discriminate amongst the list of candidates.

450 *Limitations due to system operation*

451 *Bias*

452 The LATS considers similarity that is expressed through text and returns candidate genera based
453 on statistical matches. The most challenging aspect of this is that genera with short
454 descriptions or diagnoses, which encompass a wide theoretical range of morphology, are very
455 likely to appear in a candidate list. On the other hand, those that are described with detailed
456 textual terms that enable discrimination, will appear in candidate lists but not with a high level
457 of statistical similarity. In mathematical terms this can be explained simply: based on a one-
458 word input from a user, the statistical distance of a 10-word diagnosis is larger than that of a 2-

459 word diagnosis, although they are semantically similar, which leads to a higher similarity score
460 for the genus with a 2-word diagnosis. Thus, it could be said that the LATS is biased against
461 genera with a diagnosis/description with a high discriminative potential.

462 Without altering the detail of diagnosis/description (which would contravene the principle of
463 non-intervention above) the best solution to such bias is to allow the palynologist access to all
464 the candidate taxa as in the principle of inclusion above, and to allow swift access to the
465 original descriptions and diagnoses. This ensures that the palynologist makes the final
466 determination with all the relevant material at his/her disposal.

467 **Further uses of the LATS**

468 As well as providing a LATS to aid a palynologist through the stages of identification, allowing
469 him/her to make the best judgements on determination with the best supporting information,
470 the information and 'understanding' that the underlying system has over a large area of
471 palaeopalynological taxonomy means that LATS could be put to more general uses. Two
472 examples follow.

473 **Synonyms**

474 In the early years of palaeopalynology many genera were named quickly, locally, sometimes
475 with limited access to global literature; and often without comparison to previously described
476 material (e.g. Fensome 1990, Traverse 1988). This led to a proliferation of synonyms; two (or
477 more) different names referring to the same taxon. Synonymy affects the accuracy of
478 biodiversity estimates, biostratigraphic correlation, macroevolutionary and palaeobiogeography
479 analyses, and the stability of scientific communication (e.g. Patterson et al. 2010). Because of
480 the 'understanding' that the LATS has of palaeopalynological taxonomy, it is capable of
481 detecting potential synonyms and indicating the priority of the name, the senior synonym,
482 which is the earliest validly published scientific name for a taxon.

483 An example is the Genus *Tethysispora* Vijaya and Tiwari (in Vijaya et al. 1988) whose diagnosis,
484 when input as a prompt to the LATS produces candidate genera with high semantic similarity
485 such as *Vallatisporites* Hacquebard 1957 and *Gondisporites* Bharadwaj 1962. If the user found
486 that there were grounds for suspecting synonymy, then *Vallatisporites* Hacquebard 1957 would
487 take priority.

488 **Distribution of genera (or taxa) in ‘morphological space’**

489 The morphological range of palynomorphs could be seen as occurring in multidimensional
490 space with dimensions like width, height, density of ornaments, and size of ornaments.

491 By creating a feature table (Table 2), all JHC diagnoses can be reorganized or parsed so that the
492 embedding model can convert the elements of descriptions into fixed-dimensional embedding
493 vectors. Furthermore, an unsupervised learning approach, such as principal component
494 analysis (PCA) or K-means clustering can be adapted to investigate genera in morphological
495 space. (Jolliffe 2005, Hartigan and Wong 1979)

Features	Description of Feature
Wall layer number	This taxonomic character concerns the number of wall layers
Cameration or cavation	This taxonomic character concerns the presence and extent of space or cavity between wall layers
Ornament type	This taxonomic character concerns the type of ornament of the surface of the palynomorph or within its wall
Shape (amb)	This taxonomic character concerns the outline of a pollen grain or spore seen in polar view
Cingulum or zona	This taxonomic character concerns the presence of an equatorial extension of the palynomorph wall: thick (cingulum), thin (zona)

496 Table 2. Spore characters

497 As an example, a table of features of spores of this type enables *Tethysispora* to be categorized
498 (Table 3).

499

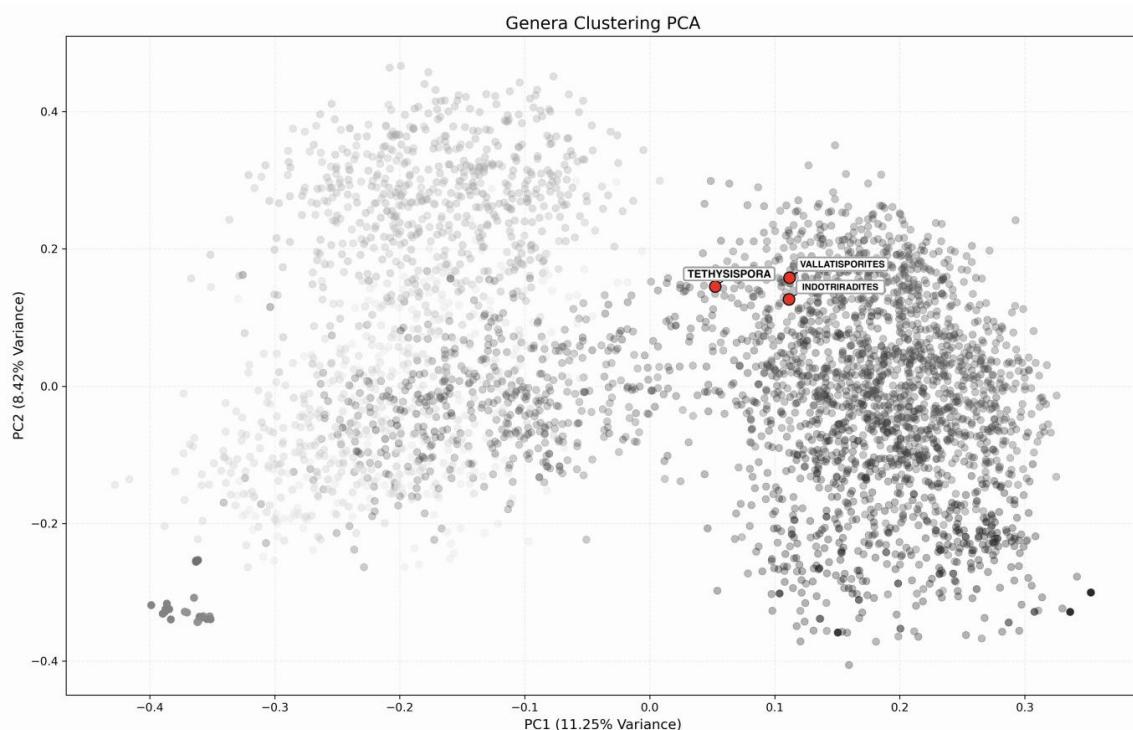

500

501

Genus name	Wall layer number and arrangement	Cameration or cavation	Ornament type	Shape (amb)	Cingulum or zona
<i>Tethysispora</i>	Exine two-layered	Cavity equatorially, distally and partly proximally within the central body, surrounding the inner body	Small, 1–2 µm regular to irregular coni; broad-based to mammoid-shaped spines with elongated, curved detachable apices also seen in some processes; processes generally sparse on distal polar region but becoming bigger and denser towards body equator; sometimes mammoid process also present along the equator of body. Ornamentation crowded on the equatorial region of the body imparting a denser appearance to the zona-base and projecting out prominently below the zona	triangular to broadly subtriangular	zona

502 Table 3. Features of *Tethysispora* Vijaya and Tiwari (in Vijaya et al. 1988)

503 A 2D-visualization for all JHC genera using PCA is shown in Fig. 9, including the candidate
 504 synonyms *Tethysispora*, *Indotriradites* and *Vallatisporites* indicating the small statistical
 505 distances between the genera.

506

507 Fig. 9. 2D-visualized morphological variation amongst JHC diagnosis with marked genera

508 Implications for LATS in other parts of palaeontology

509 The use of artificial intelligence is likely to increase in palaeontological taxonomy. Perhaps the
510 most rapid development is in image recognition based on learning from very large numbers of
511 high-resolution images of specimens without direct reference to authoritative text-based
512 diagnoses or descriptions of taxa (e.g. Niu et al. 2024). Though valuable, this method places
513 expert validations between the user and the first-principle taxonomic information. Thus, a LATS
514 has a special role in providing direct access to authoritative text-based diagnoses or
515 descriptions of taxa and we believe should be encouraged as a useful aid to professional
516 taxonomists and as a pedagogic tool for educators.

517 Many of the challenges and opportunities illustrated in this study of the conversion of a
518 palaeopalynological dataset into LATS will be similar for other fossil groups. Much
519 palaeontological taxonomic information is disparate and varies in quality and detail or may be
520 unavailable to many as it is locked behind a paywall. In palaeontological groups with a long
521 history of research, for example the brachiopods, the original peer-reviewed literature also
522 contains variation in the meaning and use of morphological terms (e.g. Williams et al. 1965).

523 The Treatise of Invertebrate Paleontology, published from 1953 by the Geological Society of
524 America and the University of Kansas provides more consistent detail. It comprises 55 volumes,
525 written by more than 300 palaeontologists, and is subdivided into a number of sections each
526 dealing with a different invertebrate animal phylum. An example is the Treatise Section Part H
527 Brachiopoda (Revised) (Williams et al. 1999-2007), a revised version of earlier brachiopod
528 volumes (Williams et al. 1965), which is one of the most complete and recently updated
529 sections of the Treatise. The work of many brachiopod specialists allowed the provision of
530 condensed, rationalised descriptions and diagnoses of 4192 genera, and offer consistent
531 morphological terminology. However, complete original (authorial) diagnoses and descriptions
532 are not provided (though are referenced).

533 The methodology used in this study may be of value to other scientists working palaeontological
534 taxonomy.

535 **Conclusions**

536 Large Language Models (LLMs), being text-based, are ideal types of artificial intelligence to aid
537 in palaeontological taxonomic determination because published textual descriptions are the
538 ultimate, authority in taxonomy. This paper describes some of the preparation required to
539 develop a database for LLM development.

540 The Jansonius and Hills palaeopalynological catalogue (JHC) is a unique record of taxonomic
541 data in palaeopalynology in that it provides original authorial diagnoses and descriptions on
542 which to train the LLM augmented taxonomic key (LATS), thus providing authoritative ‘first
543 principle’ taxonomic information.

544 The LATS functions through Retrieval Augmented Generation (RAG) and returns candidate
545 genera with statistical measures of match against the prompt(s) or users’ descriptions.

546 The advantages of the use of the LATS include rapid access to statistically relevant candidate
547 genera, including the authorial diagnoses and descriptions, which allows the taxonomist to
548 make efficient and accurate determinations. The LATS also supplies information on the
549 structures and methods of taxonomy and thus has pedagogic value, as well as broader research
550 value in the theory and concepts of taxonomy.

551 The development of the LATS described here has implications for other palaeontological groups
552 in terms of the text basis of their taxonomy (for example variable quality of descriptions and
553 inconsistency in terminology), and their suitability for development of other LLM-assisted
554 taxonomic aids or keys.

555 **Acknowledgements**

556 We acknowledge the help of the University of Calgary and the permission of the Jansonius
557 family in the development of this project.
