16 reviewed.

17

18 **Abstract**

19 Hydroinformatics and water data science topics are increasingly common in university graduate
 20 settings through dedicated courses and programs as well as incorporation into traditional water
 21 science courses. The technical tools and techniques emphasized by hydroinformatics and water data
 22 science involve distinctive instructional styles, which may be facilitated by online formats and
 23 materials. In the broader hydrologic sciences, there has been a simultaneous push for instructors to
 24 develop, share, and reuse content and instructional modules, particularly as the COVID-19 pandemic
 25 necessitated a wide scale pivot to online instruction. The experiences of hydroinformatics and water
 26 data science instructors in the effectiveness of content formats, instructional tools and techniques, and
 27 key topics can inform educational practice not only for those subjects, but for water science
 28 generally. This paper reports the results of surveys and interviews with hydroinformatics and water
 29 data science instructors. We address the effectiveness of instructional tools, impacts of the pandemic
 30 on education, important hydroinformatics topics, and challenges and gaps in hydroinformatics
 31 education. Guided by lessons learned from the surveys and interviews and a review of existing online
 32 learning platforms, we developed four educational modules designed to address shared topics of
 33 interest and to demonstrate the effectiveness of available tools to help overcome identified
 34 challenges. The modules are community resources that can be incorporated into courses and modified
 35 to address specific class and institutional needs or different geographic locations. Our experience
 36 with module implementation can inform development of online educational resources, which will
 37 advance and enhance instruction for hydroinformatics and broader hydrologic sciences for which
 38 students increasingly need informatics experience and technical skills.

39 **1 Introduction**

40 In an increasingly data intensive world, researchers and practitioners in water sciences need to apply
 41 data-driven analyses to address emerging problems, to explore theories and models, and to leverage
 42 growing datasets and computational resources. Within hydrology and related fields in environmental
 43 and geosciences, observational data are increasing in scope, frequency, and duration, and
 44 computational technologies are essential to solving complex problems (Chen and Han, 2016).
 45 Without training, students are unprepared to work or conduct research centered around large and
 46 complex data, questions, and tools (Merwade and Ruddell, 2012). To meet this need,
 47 hydroinformatics and water data science have been growing as specific topics of instruction, both in
 48 university programs and in community education settings (e.g., Consortium of Universities for the
 49 Advancement of Hydrologic Science, Inc. (CUAHSI) Virtual University and University of
 50 Washington WaterHackWeek) (Burian et al., 2013; Popescu et al., 2012; Wagener et al., 2021). In
 51 parallel, incorporation of technical tools in traditional water science courses is growing, though
 52 uptake has been uneven and lags behind what many see as needed (Habib et al., 2019; Lane et al.,
 53 2021). Hydroinformatics and water data science both combine computational tools and water-related
 54 data to achieve actionable knowledge. Although the fields are overlapping, there are subtle
 55 differences, and both terms are used throughout this paper.

56 Within the geosciences, there is increased focus on reusability and reproducibility of research data,
 57 code, and results, as well as educational materials (Ceola et al., 2015). Several online spaces have
 58 emerged as hubs for storing and sharing lectures, code, examples, and scripts developed by
 59 instructors in hydrology, water resources, and other geosciences (Habib et al., 2019, 2012; Lane et
 60 al., 2021). The widespread shift to online education resulting from the COVID-19 pandemic
 61 illustrated the value of online instructional materials and rapidly accelerated development and
 62 transition to online formats. Community educational resources, online platforms, and increased

63 accessibility of digital tools offer an opportunity to more fully incorporate informatics tools and
64 techniques for data-driven hydrologic applications into water science education.

65 This paper reports on the current state of hydroinformatics and water data science education in the
66 United States based on available literature and qualitative interviews and surveys with instructors of
67 relevant courses. Another objective of this work was development of online educational modules and
68 evaluation of the implementation platform to share insights with other instructors. Study participants
69 offered information about key topics and technologies, formats and methods of delivery, challenges
70 and gaps, and impacts of COVID-19 on instruction. In addition to the results of the survey, we
71 performed a functional review of online educational platforms based on participants' criteria. Their
72 perspectives and our evaluation were used to inform the development of online learning modules that
73 address some of the identified challenges and gaps while demonstrating existing tools. The modules
74 are community resources that can be incorporated into any related course, workshop, or educational
75 program. They are a step toward sharing educational resources for reuse not only by instructors that
76 specialize in hydroinformatics, but to incorporate informatics skills and topics more broadly in water
77 science courses. The lessons learned from platform feature evaluation and module implementation
78 are valuable for instructors sharing content and for further platform development.

79 In Section 2, we present a literature review of hydroinformatics and water data science education,
80 including best practices for sharing educational content and outstanding gaps. Section 3 outlines the
81 procedures and literature-informed questions of the surveys/interviews and the methodology for
82 development of educational modules. In Section 4, we present survey results and the key points that
83 drove the design and implementation of learning modules. Section 4 also covers a review of existing
84 online platforms and module implementation successes and challenges. Section 5 offers conclusions
85 and an outlook for the future of hydroinformatics and water data science instruction.

86 **2 Background**

87 **2.1 Hydroinformatics and Water Data Science**

88 In an early conceptualization, hydroinformatics was described as encompassing computational tools
89 to transform water related data and information into useful and actionable knowledge (VanZuylen et
90 al., 1994). Although hydroinformatics may be technical in nature, water issues are inherently social,
91 and consideration of human factors for the presentation and dissemination of results and information
92 is a key component (Celicourt et al., 2021; Makropoulos, 2019; Vojinovic and Abbott, 2017). More
93 recently, the definition of hydroinformatics is broadening to encapsulate water science, data science,
94 and computer science (Burian et al., 2013; Chen and Han, 2016; Makropoulos, 2019; Vojinovic and
95 Abbott, 2017). The objective of data science is application of analytical methods and computational
96 power with domain understanding to transform data to decisional knowledge (Gibert et al., 2018;
97 McGovern and Allen, 2021). When applied to the water domain, this definition is very close to that
98 of hydroinformatics, and for most practical purposes, it is difficult to draw boundaries between
99 hydroinformatics and water data science.

100 Based on the increasing volume, variety, and availability of data sources and the advancement of
101 software and hardware tools, there is opportunity and need for the application of data science to
102 water, environmental, and geoscience domains (Burian et al., 2013; Gibert et al., 2018). Hydrologic
103 science is shifting from collecting data to support existing conceptual models toward analyses based
104 on models derived from observational data (Chen and Han, 2016). In this paper, we report on how
105 current instructors of hydroinformatics and water data science define their fields and the topics and
106 technologies that are growing in importance in these fields.

107 2.2 Hydroinformatics and Water Data Science Education

108 Without training in data intensive approaches with modern technological tools, students will be
109 unprepared to solve emerging water problems (Lane et al., 2021; Merwade and Ruddell, 2012).
110 Technology integration and data and model-driven curriculum are key components for advancing
111 hydrology education (Ruddell and Wagener 2015). Many have recommended educational pedagogies
112 for hydrology that are “student-centered” or “problem-based”, which describe applications that
113 deepen learning by connecting to real-world contexts (Habib et al., 2019; Maggioni et al., 2020;
114 Ruddell and Wagener, 2015; Wagener and McIntyre, 2007). Students need to learn using real-world
115 datasets, actual tools, and open-ended problems, also referred to as “ill-defined”, “authentic”, or
116 “experiential” (Burian et al., 2013; Lane et al., 2021; Maggioni et al., 2020; Ngambeki et al., 2012).

117 Hydroinformatics was initially taught in the mid-1990s to enable engineers to apply information
118 technology to complex water problems (Abbott et al., 1994). Specific programs have since developed
119 including courses for professionals (Popescu et al., 2012) and graduate students (Burian et al., 2013)
120 and complete doctoral programs (Wagener et al., 2021). However, hydroinformatics courses remain
121 limited, and to gain informatics skills, students often rely on technology incorporated into traditional
122 hydrology courses, pursue self-learning (e.g., online courses, tutorials, etc.), or enroll in computer
123 centric courses that do not address the focused set of topics with domain-specific applications
124 covered by hydroinformatics.

125 Training in data science is typically separate from domain sciences; however, data science curricula
126 cannot adequately address domain knowledge, so students are expected to rely on their own
127 “substantive expertise” (Grus, 2015). Voices in industry and academia are calling for well-rounded
128 and technology-literate water scientists (Chen and Han, 2016; McGovern and Allen, 2021), which
129 may be achieved by packaging informatics and/or data science topics with real-world water science
130 applications (Gibert et al., 2018; Wagener et al., 2021). In this paper, we use information gathered
131 from instructors to understand how courses are being taught, what techniques are successful, and
132 what would be useful going forward.

133 2.3 Sharing Educational Content

134 As technology and applications advance, books and even online content may become outdated
135 quickly, and hydroinformatics and water data science instructors are challenged to keep up
136 (Maggioni et al., 2020; Makropoulos, 2019; Wagener et al., 2007). Given shifts toward big data, open
137 data sources, reproducible research, and data-driven analysis, many have called for advancement in
138 content for teaching water science and methods for delivery of that content (Habib et al., 2019;
139 Seibert et al., 2013). The COVID-19 pandemic caused many courses to be moved to virtual
140 platforms, prompting evaluations of instructional formats and a call for additional online educational
141 material (Maggioni et al., 2020).

142 Community platforms and resources can advance water science instruction by facilitating data-driven
143 learning and offering common principles and approaches for teaching (Makropoulos, 2019; Merwade
144 and Ruddell, 2012; Popescu et al., 2012; Wagener et al., 2012). Although water science modules
145 have been shared and published online (e.g., Habib et al., 2012; Wagener et al., 2012), without
146 integration within a common platform, modules are difficult to identify, access, and implement. In
147 2012, Merwade and Ruddell noted that an appropriate system was not yet in place, and there remains
148 no single clearinghouse of educational resources in the field. More recently, Lane et al. (2021) and
149 Maggioni et al. (2020) developed and published course content via HydroLearn
150 (<https://www.hydrolearn.org/>). Lane et al. (2021) made the case that online educational materials

151 should be supported by active learning, basic templates, adaptation, multiple content types, and
 152 pedagogical tools, which make HydroLearn an effective platform. To these functional capabilities,
 153 we add that systems need to offer persistence as we were unable to access many of the online
 154 resources that were reported in the literature. They were either missing completely, lacking crucial
 155 metadata, or using outdated software or systems.

156 Our review of the literature identified key components, guidelines, and best practices for sharing
 157 educational content along with gaps and opportunities to improve. In this paper, we also consider key
 158 components to successful online modules as identified by hydroinformatics and water data science
 159 instructors, which we used as criteria to select an online educational platform. Based on these
 160 findings, we describe the development and implementation in an online system for four modules
 161 focused on hydroinformatics and water data science, which are available for instructors adapt into
 162 courses and may serve as examples to the community.

163 **3 Methods**

164 **3.1 Survey and Interview Methodology**

165 We developed survey and interview questions that focused on the instructors' courses and their
 166 perspectives on the future of the field (Table 1). Participant responses were analyzed to identify
 167 common themes surrounding key research questions: 1) What is the current state of instruction in
 168 hydroinformatics and water data science, including the effectiveness of tools being used for in-person
 169 and online instruction?; 2) How has the COVID-19 global pandemic affected instruction?; 3) Which
 170 topics comprise hydroinformatics education and what topics are growing in importance?; 4) What are
 171 the major challenges in hydroinformatics instruction?; and 5) How can shared instructional resources
 172 be beneficial for instructors and students? Although this analysis was primarily qualitative, where
 173 commonalities emerged, we were able to tally responses and present quantitative results.

174 Potential participants were initially identified via investigator connections, review of relevant
 175 literature, and information on institutional and personal websites discovered by Internet searches.
 176 Target participants were selected based on their experience teaching hydroinformatics, water data
 177 science, or related subject matter at an institution of higher education. We used email to invite
 178 contacts to participate, and participants elected to respond to questions either via online survey or
 179 recorded interview. During each interview or survey, participants were asked to identify any
 180 additional instructors who might be a good fit for the project.

181 While the questions for surveys and interviews were the same, both approaches were used so that
 182 participants could choose their preferred mechanism to respond. We acknowledge that the different
 183 modes for data collection may have influenced the length or character of the responses, but we made
 184 this decision to maximize the potential for participation. We observed that content specificity did not
 185 differ greatly between surveys and interviews. The survey was composed using Qualtrics software
 186 and administered with links personalized for each participant. Interviews were conducted over Zoom,
 187 recorded, and subsequently transcribed. Each interview lasted approximately 45-60 minutes. Notes
 188 were taken during all interviews in case of issues with audio. A total of 18 instructors participated in
 189 interviews (n=7) or responded via survey (n=11). Herein, we refer to interview and survey
 190 participants as "participants" and do not differentiate between the mode in which they participated.
 191 Procedures were approved by the Utah State University Institutional Review Board for Human
 192 Subjects Research with participation limited to instructors within the United States.

193 **3.2 Review of Educational Platforms and Modules**

194 From participants and our own review, we identified several existing online platforms for sharing
 195 educational content. Using the survey and interview responses, we extracted characteristics that
 196 participants considered important in an online platform for depositing materials and used these to
 197 assess available options. We identified specific instances of educational materials from the
 198 hydroinformatics community that are available online for each of the considered platforms.

199 **3.3 Module Development**

200 We evaluated educational platforms based on the criteria identified in interview and survey results to
 201 determine the repository and format to use for depositing the educational modules developed as part
 202 of this work. At a minimum, we required that modules be implemented in an open access format. Our
 203 selection of a particular platform does not signify that it should be preferred for all instructors,
 204 courses, or learning situations, and we anticipate that instructors will adapt content to their preferred
 205 interface.

206 We used the suggestions from participants to inform the topics for the educational modules
 207 developed as part of this work. Given the breadth of suggested topics, our team could not develop
 208 modules to comprehensively cover all areas. This points to the need for community resources to take
 209 advantage of the varied teaching and research expertise of instructors. Rather than serve as a
 210 complete and unified set of educational content, the modules we developed act as a demonstration
 211 and a launching point for sharing content.

212 Our conceptual model of a learning module independent of any specific technological
 213 implementation consists of the following elements: 1) learning objectives, 2) narrative, 3) example
 214 code, and 4) technical assignment. The learning objectives guide the content that is presented through
 215 the other elements and may be contained separate from or as part of the narrative. The narrative
 216 covers the core of the concepts and topics and is communicated through various formats – e.g.,
 217 slides, documents, and/or video. Example code may take the form of scripts, formatted markdown or
 218 text, or an interactive code notebook. Technical assignments consist of authentic, open-ended tasks
 219 based on real-world data that require students to implement code and write a descriptive summary.
 220 Authentic tasks are high cognitive-demand activities designed to reflect how knowledge is used in
 221 real life and to simulate the type of problems that a professional might tackle. Authentic tasks have
 222 no single answer and thus avoid concerns with publicly available solutions and achieve higher level
 223 learning objectives. Each assignment includes a grading rubric to ensure that expectations and
 224 evaluation criteria are clearly defined and activities are aligned with learning objectives, outcomes
 225 and assessment, referred to as constructive alignment (Kandlbinder, 2014).

226 **4 Results and Discussion**

227 **4.1 Survey and Interview Results**

228 Each instructor’s definition of the terms “hydroinformatics” or “water data science” was unique, but
 229 all centered on common themes of using computers and informatics tools to solve water problems,
 230 including data collection, storage, sharing, interpretation, analysis, synthesis, and modeling. One
 231 participant simply defined hydroinformatics as “*data and water*”. The following quote summarizes
 232 the motivation for teaching these subjects:

233 *“We have...talented, quantitatively savvy people...engineers and geologists and hydrologists*
 234 *and scientists that live and breathe data analysis and are limited by the tools they use. And we*
 235 *also have increasing data volume and aging infrastructure, emerging pollutants, drought,*

236 *climate change. There [are] so many challenges our field faces. So, the goal is to give people*
 237 *modern tools to deal with modern water data challenges.”*

238 The interviews and surveys generated a rich body of results, which we distilled in view of our core
 239 research questions. The current state of instruction in hydroinformatics and water data science is
 240 addressed in Section 4.1.1, including platforms, modes of delivery, and impacts related to the
 241 COVID-19 pandemic. As the pandemic prompted shifts to online platforms, Section 4.1.2 focuses on
 242 the effectiveness of tools for online instruction. Section 4.1.3 reports on the topics and technologies
 243 that comprise hydroinformatics education. Challenges and future directions of hydroinformatics
 244 instruction are covered in Section 4.1.4. Section 4.1.5 addresses interest, considerations, and potential
 245 benefits of shared instructional resources. In the following results, the number of participants (out of
 246 18 total) that correspond to each response is reported parenthetically.

247 **4.1.1 Courses, Platforms, and Modes of Delivery**

248 The courses taught by participants include hydroinformatics and related courses with emphases on
 249 data science, research computing, and data and analysis tools (see Table 2). Most of the courses
 250 taught by participants are directed to university graduate students (14), though a few are
 251 undergraduate Introduction to Data Science classes (2), several courses are a mix of undergraduate
 252 and graduate students (4), and a few are designed for professionals (2). Most of the graduate classes
 253 permit some undergraduate enrollment, and several instructors noted that students at their institutions
 254 are exposed to some hydroinformatics topics in lower-level hydrology or geographic information
 255 system (GIS) classes.

256 Most of the courses are conducted in-person, although some had an online component even prior to
 257 COVID-19. In total, 12 out of 18 participants teach courses in person. Of these, most moved to an
 258 online format because of the COVID-19 pandemic. A few instructors (4) did not teach during this
 259 period due to buyout, sabbatical, or changing institutions. Multiple instructors (3) developed courses
 260 during the pandemic that would normally be held in-person. Of the courses offered fully online (6),
 261 one is a course for professionals, one was offered through an online community college, one was
 262 designed for a virtual university, and the remaining 3 are taught through universities.

263 Of those participants who moved from in-person to online because of COVID-19, most did not
 264 significantly change course structure but continued to use a format consisting of lectures with slides
 265 and coding demonstrations. Some instructors held synchronous classes over Zoom while others
 266 recorded lectures for asynchronous viewing. Additional modifications to address challenges of online
 267 learning are described in Section 4.1.2. Although hydrology and hydroinformatics have been
 268 identified as well-suited for online instruction (Merwade and Ruddell, 2012; Popescu et al., 2012;
 269 Wagener et al., 2012), even technologically savvy instructors with informatics-focused curriculum
 270 were generally returning to in-person formats even before the COVID-19 pandemic was over. The
 271 return to in-person instruction may be related to institutional expectations and instructors’
 272 preferences rather than ineffectiveness of tools and technologies. However, several instructors
 273 perceived benefits to online aspects and reported adjusting their teaching formats accordingly. A
 274 handful plan to shift modalities to alternate in-person and online classes or to a flipped format where
 275 lectures are recorded and viewed asynchronously while in-person class periods are work sessions.
 276 One participant was pleased with outcomes from online instruction and planned to continue with a
 277 purely online format.

278 Instructors reported implementing a wide range and multiple layers of educational platforms to
 279 support instruction and handle course materials. Out of 18 participants, most (16) used a learning

280 management system (e.g., Canvas, Blackboard, Brightspace, Sakai) for grading and assignment
 281 submission. For messaging with students, some used Canvas (or similar), though several instructors
 282 reported success in transitioning all course communication to Slack (2). For some, the learning
 283 management system was used to share files, while others stored and shared code and datasets with
 284 repositories in GitHub (6) and HydroShare (4), and a few reported using email or Google Drive. All
 285 these platforms were generally reported to be effective for both in person and online instruction, and
 286 several instructors planned to continue using Slack when returning to in-person instruction.

287 Most of the participants reported conducting live coding during lectures, whether synchronous or
 288 asynchronous, online or in-person. Some instructors switch between traditional teaching material
 289 (e.g., slides, videos) and live coding while others exclusively use coding interfaces for instruction.
 290 Many instructors (6) reported teaching with code notebooks (e.g., Jupyter) that can be launched from
 291 a web browser and include text and images as scaffolding to explain and support the code. Some
 292 instructors reported advantages to using GitHub and Jupyter notebooks:

293 *“Jupyter notebooks enable us and our students to have a conversation with a problem and*
 294 *link to resources, like audio, video, images, visualizations and implement water resources*
 295 *projects step by step.”*

296 *“Jupyter notebooks work great for teaching either online or in person... They are especially*
 297 *nice for students working through in-class exercises. We...share screens while the instructor*
 298 *or students work through problems.”*

299 *“...copying [the assignment] to my private [GitHub repository] for grading and...deleting*
 300 *...the code that the students need to fill out but leaving the results...then committing those to*
 301 *the public repo [is]...a great tool...because [they] know what the answer should look like. ...*
 302 *there's...self-training and...self-evaluation...by...working on their code until they get it to*
 303 *look like what it should.”*

304 **4.1.2 Challenges and Benefits of Online Delivery**

305 The most reported challenges for online delivery were interpersonal and not unique to
 306 hydroinformatics or water data science. Instructors were concerned about meaningful engagement
 307 with students, lack of feedback and participation during lectures, and students struggling without the
 308 camaraderie and accountability of an in-person instructor and classmates.

309 *“...a lot of tactile things...are lost in a virtual format, and that can be very frustrating for*
 310 *students and instructors and really slow the course down.”*

311 *“You ask a question, and there's no feedback. You don't see anybody's faces. You don't hear*
 312 *any response. ...you have to force those interactions and knowledge checks through some*
 313 *other mechanism.”*

314 Instructors also reported difficulties with determining the best formats and technologies for rapidly
 315 pivoting to online instruction and the time-consuming nature of creating high quality online content.
 316 Reduced interaction and the time required for instructors to develop content are established
 317 drawbacks to online learning (Habib et al., 2019; Wagener et al., 2021).

318 A concern expressed by multiple instructors (6) specific to computer-based classes was the difficulty
319 of troubleshooting and reviewing code and errors without being able to crowd around the screen.
320 Another issue for several instructors was getting hardware and sensors into the hands of students.

321 *“...during the hands-on lab, I stop by each student and see if they're following and if they can*
322 *finish that specific section of the code. ...But in Zoom, it's relatively harder to see all the*
323 *screens and then go back to each one...a classroom environment is often very engaging and*
324 *more hands on for students. They can easily talk to the person next to them and get some*
325 *help.”*

326 *“Live coding is challenging because students don't often have multiple screens, so typing*
327 *code while watching the lecture requires some careful window manipulation.”*

328 To address these challenges, instructors adjusted to hold more office hours and help sessions and
329 increase communication opportunities:

330 *“I polled students [to ask] what's going on? What are the pain points? ...they really enjoyed*
331 *being able to watch stuff on their own time. So instead of doing a live lecture, I ended up*
332 *doing recordings and then during the lecture times I [held] office hours. In fact, I started*
333 *doing...office hours at...9pm, 10pm. It was crazy how busy they were.”*

334 *“We do a lot of office hours due to COVID so that we can connect, look at their*
335 *screen...What's the problem with their code? I increased [office hours], but also, I schedule*
336 *meetings with students if they have a [specific] problem...it's not really that engaging as in*
337 *person, but still, we try to support the missing pieces...through some online meetings.”*

338 Participants reported that communicating expectations for online classes and deliberately facilitating
339 interaction helped ensure student engagement.

340 *“We make it a point to tell students that being in an online class is no different than being*
341 *face-to-face in terms of being engaged or not. ...This helps the students get to know each*
342 *other and learn how to navigate online meetings, which is a great professional skill to*
343 *develop. We are also more intentional in encouraging community in the online class; I have*
344 *an "ice breaker" question related to data science each day, and many students submit their*
345 *answers in the chat window.”*

346 Despite the challenges of online delivery, instructors deemed several aspects of online instruction as
347 beneficial. Zoom was an effective technology for interactive remote instruction, and several
348 participants preferred live coding via Zoom rather than in the classroom because students could more
349 easily follow along and screenshare their own work. For some participants, Zoom breakout rooms
350 facilitated group work.

351 *“If anything, the class may have gone more smoothly this way because everyone was sitting*
352 *at a computer all the time so we could more easily screen share and debug and demonstrate*
353 *across the instructor and student machines.”*

354 *“There are some elements of being online that work really well for this class. ...The course is*
355 *...flipped, so each professor prepares ...videos for the students to watch in advance, and they*
356 *also prepare a set of in-class exercises. During class, we split the students into breakout*
357 *groups of 4-5 students each, and they work on the exercises. The professors and TA circulate*

358 *through the rooms answering questions. At the end of the class period, we reconvene to*
 359 *discuss interesting problems or issues that arose while the students worked.”*

360 Even with a return to in-person instruction, some are retaining approaches that were successful
 361 during the online period. These adjustments include non-traditional modalities for
 362 synchronous/asynchronous lecture and work sessions and increasing the use of tools and platforms
 363 such as Zoom, Slack, and Jupyter notebooks.

364 **4.1.3 Content, Technology, and Topics**

365 All participants reported creating custom materials for their course and/or adapting content from
 366 other sources. A majority (13) created most of the instructional materials for their course. Only a
 367 handful (4) used any textbook: one hydroinformatics text, one modeling text, one statistics text, and
 368 one converted an existing coding book to water resources examples. A reported challenge is the
 369 rapidly evolving nature of the field in which the technology and applications change faster than
 370 published textbooks can account for. Several instructors (4) borrowed, exchanged, or modified
 371 material from each other.

372 *“I have created all of my own course materials. I do not use a text. Most materials were*
 373 *drawn directly from my own research and project experience or that of my close colleagues.”*

374 *“We have built up the course material from scratch...we were not aware of a...textbook that*
 375 *would teach the students at the level that we wanted and with the types of R programming*
 376 *that we wanted while illustrating with the water-related data that we wanted.”*

377 Regarding technologies emphasized, almost all instructors teach coding in Python (10) or R (6). In
 378 addition, instructors cover structured query language (SQL) (4), ArcGIS (3), Arduino (3), and web
 379 technologies (i.e., PHP, JavaScript, HTML, CSS) (3). For several cases, the course evolved from
 380 using Matlab to R to Python so that students have experience in a non-proprietary coding language
 381 that they can use in subsequent settings regardless of affiliation.

382 *“I had a student who was just an outstanding computationalist. ...got a great job...came back*
 383 *and she said...I really loved your class and I wish I still had...the ability to do those kinds of*
 384 *analyses, but our company won't pay for the MATLAB license...it was just heartbreaking*
 385 *because...think about what your company is missing out on by you not being able to do*
 386 *that...I [determined I] really...need to move this to Python or something that they're going to*
 387 *continue to have access to, regardless of where they work in the future.”*

388 Although hydroinformatics is centered on tools, rather than emphasizing specific technologies,
 389 participants emphasized teaching students how to learn new informatics tools, a finding that echoes
 390 the emphasis of Burian et al. (2013). Several instructors noted that hydroinformatics technologies
 391 continue to advance, which makes it hard to settle on a set of tools to use in teaching a course and
 392 highlights the need to teach students how to recognize which tools to use in different scenarios.

393 *“Students might never use those specific tools again, but have skills to learn new tools.”*

394 *“I do not expect that students leaving my class will be experts in any of these skills. However,*
 395 *they should have explored each of them and developed a level of proficiency that they know*
 396 *which of them will be the most useful in their research and future careers and which may be*
 397 *the most important for them to invest further time and effort into becoming more proficient.”*

398 *“I think we have reached a point where there are relatively good cyberinfrastructure*
 399 *components out there in the hydroinformatics domain and now one of the bigger problems is*
 400 *composability - e.g., how can students and researchers learn all of the available tools and*
 401 *then decide which tools to put together in composing a research, data analysis, data science,*
 402 *modeling, etc. workflow.”*

403 Other instructors emphasize data and project management skills, which are agnostic to specific
 404 technologies or tools.

405 *“My expectations for the informatics skills...are...more about...habits of mind and*
 406 *computational practices around...reproducibility and...sustainable code...making sure that*
 407 *their code is under version control, making sure that they're using things like Jupyter*
 408 *notebooks to provide...traceable and reproducible demonstrations of their workflows, more*
 409 *so than any kind of specific technique that they're using.”*

410 An important skill repeated by participants was appropriate troubleshooting, including understanding
 411 documentation and finding help through forums and other resources.

412 *“We...encourage students to use the internet to help them work through problems and*
 413 *troubleshoot coding errors (e.g., Google, StackOverflow).”*

414 Each instructor and each course have specific emphases. While there is variety in what is taught, the
 415 overlap of common subjects illustrates key topics and themes that currently comprise
 416 hydroinformatics instruction (Figure 1). Most instructors (13) focus on scripting and coding basics
 417 (in Python, R, or Matlab) with emphases on data formatting, manipulation, and wrangling (12) and
 418 data visualization and plotting (11). Data science (10), basic statistics (7), and machine learning
 419 topics (7) were commonly mentioned. About half of participants covered geospatial topics such as
 420 mapping (7) and spatial analysis (10), which some instructors view as essential while others exclude
 421 these topics as they are covered by other courses. Several participants (6) include instruction on
 422 workflows, reproducibility, and best practices for coding. Other topics mentioned by multiple
 423 instructors included databases, data models, and SQL; dataloggers and sensors; modeling; the data
 424 life cycle and metadata; Git; and web services and web mapping tools.

425 Because of the open-ended nature of the questions, these numbers should be interpreted generally –
 426 e.g., more instructors may include content on metadata but did not explicitly mention it. Similarly,
 427 “modeling” is a broad term with various meanings and implementations. Despite these limitations,
 428 we can identify a few important takeaways. First, hydroinformatics is broadening its focus from
 429 modeling with custom tools and graphical user interfaces (GUIs) (as described in many of the papers
 430 we reviewed) to more strongly emphasize data management, visualization, and analysis using open-
 431 source scripting tools. These capabilities provide a broader path for addressing water-related
 432 challenges and questions.

433 *“[The] basics of how to organize, use, and process data has not changed, but the technology to*
 434 *do that keeps changing. For example, we no longer use interface or GUI... The term workflow*
 435 *was not used earlier but is now used frequently. There is more use of internet-based tools and*
 436 *publicly available/open-source tools.”*

437 *“Things are becoming more standard; the tools keep getting better. We are now able to use*
 438 *mostly open-source mainstream languages and tools for our specialized environmental*
 439 *informatics work; 20 years ago we needed to build and use clunky, custom-purpose tools. This is*

440 *much better now. It also means, however, that there is less need for 'hydroinformatics' specific*
 441 *tools and methods."*

442 Second, a primary objective for many of the instructors was to ensure that students are comfortable
 443 working in one scripting language and understanding the basic concepts of functions, conditional
 444 statements, iteration, logical operation, data management, querying, and visualization. Any modeling
 445 being taught is within the context of open-source scripting environments. We observed that data
 446 science, statistics, and machine learning topics are generally being taught in the water data science
 447 courses while databases, sensors, and spatial analyses are being taught in strictly hydroinformatics
 448 classes. However, the crossover between these topics is growing, and the boundaries between
 449 hydroinformatics and water data science are fuzzy.

450 Third, several instructors emphasize communicating scientific data and results, and others focus on
 451 enabling students to translate the skills gained in the course to resume entries or digital code
 452 portfolio.

453 *"I'm big on science communication...that was the first time that they had ever really had*
 454 *someone be pedantic enough to talk about presentation of data, quality of graphs, quality of*
 455 *the writing."*

456 *"I try to work with them to put it on their resume in a way they can explain it. ...they're*
 457 *getting some really cool jobs...they wouldn't have gotten, as a result...So it basically opens up*
 458 *career trajectories that are not just typical civil and environmental consulting."*

459 *"At the end of the class I'm hoping that they have...a GitHub repository that has...Jupyter*
 460 *notebooks that are their problem sets that they feel comfortable sharing on their LinkedIn*
 461 *profile or their CV that [is] a small e-portfolio of a demonstration of things [they] can do*
 462 *computationally."*

463 **4.1.4 Challenges And Future Directions**

464 There was little consensus in identified challenges and future directions (Figure 2), which reflects our
 465 finding that instructors are developing their own content based on their own definition of the field,
 466 drawing from their own research and experience. Many participants identified machine learning,
 467 deep learning, and/or artificial intelligence as increasingly relevant, reflecting the growing use of
 468 these techniques in water science (McGovern and Allen, 2021; Nearing et al., 2020; Shen, 2018).
 469 Beyond covering those topics broadly, some instructors offered specific ideas, including better
 470 understanding why some techniques do or do not work for some datasets, addressing correlation in
 471 data, and using data-driven modeling with physics-informed machine learning. Sensors and
 472 hardware-related subjects were identified as important by many participants, including managing
 473 high frequency data, low power and ubiquitous sensing, and smart sensors with controls and
 474 feedback for real-time decision making. Participants also mentioned electronics, drones, and satellite
 475 data. Data management aspects included data quality, reproducible analyses, big data, database
 476 schemas and SQL, and collaborative version control (e.g., GitHub).

477 *"So there's always going to be an importance in a baseline proficiency in working with*
 478 *tabular and spatial data within water resources data science. ...as data volumes increase,*
 479 *then you need...database skills, so creating schemas, interacting with databases, whether*
 480 *that's Postgres on a cloud or [SQLite] on your local computer. ...something [that will] hold*
 481 *really big volumes of data, and then interact with it in a structured query language."*

482 One participant noted that web applications are overtaking desktop applications, further evidenced by
 483 several participants identifying cloud computing and technologies as an area of growing importance.
 484 For geospatial topics, emerging applications include open technology and platforms (e.g., Google
 485 Earth Engine) and open remote sensing products. Although visualization is covered in most of the
 486 courses, several participants noted that creative, interactive visualization tools and dashboards are
 487 increasingly important.

488 The range of responses regarding topics of growing importance demonstrate that these subjects are
 489 broad and varied, and that the tools, technologies, and topics continue to evolve, compelling
 490 instructors and courses to be agile. The challenge of defining and teaching a moving target was
 491 reiterated by several participants. Despite the long list of possible topics to cover in a course, one
 492 participant suggested that simplifying to cover fewer tools and models is preferable. Given the
 493 inflexibility of most engineering and science degree curricula and class structures, it is unlikely,
 494 outside of specifically focused degree programs, that additional hydroinformatics and water data
 495 science classes will proliferate in most university settings. However, it is feasible, and arguably
 496 preferable, that hydroinformatics and data science topics be better incorporated into other existing
 497 courses.

498 *“Students have told me previous versions of this course was foundational for their PhD/MS*
 499 *and that it was ‘the most useful course I have ever taken’. They appreciated...the hidden*
 500 *curriculum (stats/R/programming) was brought to the forefront in my classes.”*

501 *“Students get very little, if any, exposure to hydroinformatics with their undergraduate*
 502 *degrees. I am in a Civil and Environmental Engineering department, and our undergraduate*
 503 *curriculum is so tight that students have very few options for tailoring their undergraduate*
 504 *degrees. Thus, many...show up in graduate school lacking the preparation for making*
 505 *advances in hydroinformatics.”*

506 A major gap reported by participants is students’ lack of baseline programming experience. Most of
 507 the courses expect some level of domain knowledge but do not require programming skill. However,
 508 getting students up to speed consumes precious time, and instructors would prefer
 509 programming/scripting at earlier levels (i.e., undergraduate). Participants reported difficulty in
 510 approaching advanced topics when students are learning to program for the first time, similar to Lane
 511 et al. (2021). Although computational skills are critical to water science and hydrology fields
 512 (Merwade and Ruddell, 2012), students are often expected to figure them out without explicit
 513 instruction (i.e., the “hidden curriculum”).

514 *“Mainly I think hydroinformatics concepts could be introduced earlier or at all in*
 515 *undergraduate education. These things are so critical to the field that I think a solely analog*
 516 *hydrology course is a disservice to students.”*

517 *“If students don't come prepared with coding competency and conceptual fluency in computer*
 518 *science, they struggle to learn the applications to environmental fields.”*

519 **4.1.5 Shared Resources**

520 Participants unanimously indicated moderate to high interest in sharing and exchanging teaching
 521 materials, and several reported already depositing educational content online. However, the materials
 522 are spread out in various formats over multiple platforms, and we were unable to locate some of the
 523 resources reported to be available. There is no single centralized platform, and implementations range

524 from files uploaded to a personal website to a fully interactive online course. Reported interest and
525 rate of uptake is uneven. One participant prepared and posted course content in a public repository
526 with no knowledge of reuse while another shared content in an interactive website and received
527 feedback from multiple external users. Even so, the level of reuse is modest relative to what some
528 participants consider necessary for high impact.

529 *“You have to make it easy and provide a venue where a significant number of students or*
530 *other faculty will pick up on content.”*

531 Despite universal interest in sharing materials, some participants expressed hesitancy to rely on
532 others’ content, to personalize and adapt it to fit their class, and to invest the time to gain the
533 expertise to present others’ materials.

534 *“I don't know that...I would have grabbed someone else's material and...taught...a course.*
535 *There's a lot of value I found as an instructor in having to prepare all the material from*
536 *scratch myself as a way of making sure I actually know what I'm talking about. ...it is very*
537 *nice to have other resources [as a] stencil of what a class might look like, and what good*
538 *topics would be...I would probably still have to spend the time to develop...a copy of that*
539 *myself so that I actually knew what I was doing.”*

540 A barrier to exchanging materials is the difficulty of knowing what modules or case studies exist, so
541 an ideal system would facilitate discovery. Other desirable qualities of a platform, as identified by
542 participants, include complete descriptions/metadata, a navigable interface, straightforward
543 functionality for adding content, and separate teacher/student access.

544 *“Some website where it is easy to search and find modules. It should be easy to navigate and*
545 *easy to add new contributions. It would be cool if you could see how other faculty members*
546 *have put together modules to create their own course.”*

547 For shared resources, instructors are interested in portable programming examples, particularly: 1)
548 Jupyter notebooks consisting of code and supporting theory and instructions in markdown, and 2)
549 GitHub repositories that can be cloned and adapted. Other suggestions included slide decks, videos,
550 handouts, example assignments, HydroShare resources, and ArcGIS online content. Participants
551 wanted modular, self-contained exercises that can be modified and swapped into classes.

552 *“Self-contained coding exercises that maybe on the first iteration can address a single*
553 *problem, but then the instructor themselves can develop the sequence of problems that are the*
554 *deeper dives after that. Something that can be easily plug and played into an existing*
555 *curriculum or into an existing lecture, and then...would encourage ownership of the content.”*

556 Similar to topics of increasing importance, topics of interest for shared resources varied (e.g.,
557 databases, interactive visualization, data-driven hydrologic models, cloud computing, etc.).
558 Regardless of topic, domain specific datasets were consistently mentioned as a key need for shared
559 resources.

560 *“The biggest [need] is domain specific data that works for the kind of examples that we need*
561 *to show...datasets that are large, complex, have hidden components in them that we're going*
562 *to find, can be used to make a case for or against something...that can serve as good*
563 *examples. And it's a slippery slope because either the dataset is too simple and it's silly. It's*
564 *like 10 data points and we're drawing a line through it. Or it's...somebody's PhD dissertation*

- 565 *and good luck getting that like into some sort of format where an undergrad can actually use*
 566 *it in the class.”*
- 567 *“Datasets that are ready to be used for illustration in class. These must have associated*
 568 *metadata that describes why the data was collected, what the researchers hoped to achieve*
 569 *with it, what each of the variables is, the sampling frequency, and what the data can be used*
 570 *to illustrate (i.e., clustering, visualization, regression, etc.).”*
- 571 Several participants recognized that licenses with clear conditions for reuse and citation would help
 572 instructors understand limitations and expectations for repurposing content.
- 573 *“...one of the best ways to learn is to look through other people's well-documented code, so*
 574 *open-sourcing the code and data used for scientific research, and using FAIR data standards*
 575 *to improve documentation and usability, is very important.”*
- 576 *“I think a GitHub with data with notebooks...that has a clear Creative Commons license for*
 577 *both the data and the notebook. And so I know I can use it, change it without getting a nasty*
 578 *gram...from someone's legal department seven years later.”*
- 579 Regarding barriers for exchanging resources, the most common response was that credit could
 580 motivate instructors to publish instructional material. This may take the form of counting toward
 581 tenure and promotion decisions, citations to document the contribution, or monetary payment – e.g.,
 582 a grant related to platform or repository development.
- 583 *“Support from universities for "teaching" efforts beyond the...classroom, and consideration*
 584 *of these efforts and outcomes (e.g., pageviews/downloads) for hiring & tenure decisions.”*
- 585 *“Money - there's a lot I think we'd all do for a small amount of money. If you pay professors*
 586 *for their time, they will engage.”*
- 587 Normalizing sharing teaching materials and developing a community around the exchange was
 588 another commonly repeated suggestion. Reciprocity was mentioned as crucial so that the exchange is
 589 mutually beneficial rather than a one-way offering.
- 590 *“...if there are ways to, outside of the traditional incentive structure of writing research*
 591 *papers, to incentivize...technologically savvy researchers, postdocs, faculty to contribute*
 592 *lessons like this, then you'll see more participation... it has to be made important and valued*
 593 *by...the community somewhere.”*
- 594 *“[I would] go through the trouble of sharing...my resources if I knew that others were*
 595 *sharing theirs and that there could be an exchange from which I could benefit. All of my*
 596 *course materials have been online and openly available for a long time. Others have asked if*
 597 *they could use them, and I have always said yes. I've never had anyone offer to let me use*
 598 *modules they have developed, so the 'exchange' part of this would be important for me.”*
- 599 Collaboration via feedback and edits on shared content was suggested, and multiple participants
 600 mentioned that workshops would be helpful to exchange ideas and build rapport.
- 601 *“This course material is available to only 25 students per year. And seeing that it is used by*
 602 *many more...by different instructors and different institutes would be a nice...outcome of all*

603 *these efforts. We really put a lot of effort for these materials to be created and used and*
 604 *refined throughout the years. ...potentially giving feedback to these material and...seeing*
 605 *some updated versions of it by other instructors...a community level refinement of the course*
 606 *materials, and creating new versions and better, maybe more up to date versions of these*
 607 *slides will be...useful.”*

608 *“It would...motivate me if I knew that my contribution would be widely viewed and/or*
 609 *utilized. A workshop that drew educators/contributors together to share could be a helpful*
 610 *place to start.”*

611 **4.2 Building Educational Modules for the Future**

612 Using information gathered on online educational platforms and examples of hydroinformatics
 613 educational content from study participants and our own search, we reviewed existing online
 614 platforms considering participant-identified attributes and selected HydroLearn for module
 615 implementation, covered in Section 4.2.1. Section 4.2.2 describes the modules developed by this
 616 work and how they address identified gaps. Module implementation is related in Section 4.2.3,
 617 including the mapping of module components to HydroLearn concepts and the benefits and
 618 challenges of implementing modules in online platforms such as HydroLearn.

619 **4.2.1 Online Educational Platforms and Materials**

620 There was no consensus among instructors on the preferred approach for sharing hydroinformatics
 621 educational material (Table 3). Some of these platforms are growing in popularity in the hydrologic
 622 science community but have not gained traction with the hydroinformatics instructors that we
 623 surveyed. The options include systems specifically designed for sharing and publishing educational
 624 content (HydroLearn, MyGeoHub, eddie, ECSTATIC), more generic repositories for data or code
 625 (HydroShare, GitHub), and customizable interfaces (personal websites, Canvas, or online courses).
 626 We reviewed these options with respect to characteristics extracted from the literature and our survey
 627 results (Table 4). Desirable characteristics include flexibility for hosting various types of materials,
 628 compatibility with open data practices, formal pedagogical structure, structured metadata, review and
 629 curation of content, and separate faculty and student access (Lane et al., 2021; Makropoulos, 2019;
 630 Merwade and Ruddell, 2012; Popescu et al., 2012; Wagener et al., 2012).

631 The major tradeoffs between the identified platforms are the level of control for creators versus
 632 structure to support education-specific content. Whereas personal websites and custom online courses
 633 allow for a great deal of specialization, regular updating, and customizable interfaces, they do not
 634 include the searchability, structured metadata, curation, and educational support offered by several of
 635 the education focused platforms. A particularly attractive feature for hydroinformatics and water data
 636 science instruction is the ability to launch and run code notebooks. Two of the platforms that we
 637 examined have Jupyter servers and can launch notebooks: MyGeoHub and HydroShare. Potential
 638 challenges with these platforms include scalability for use with classes of students, inclusion of data
 639 files that accompany code, and installing desired software packages. Although existing systems
 640 currently do not support all desired functionality, we anticipate those limitations will be overcome
 641 with future development.

642 In deciding which platform to use for the educational modules of this work, we considered the factors
 643 in Table 4 with a focus on reuse and collaboration. We deposited materials in HydroLearn as it
 644 facilitates export and adaptation of courses and includes metadata, citation, curation, and pedagogical
 645 structure. HydroLearn is a repository for instructional material related to hydrology and water

646 resources. Developed on the edX learning management system, HydroLearn is designed to support
 647 collaboration around instructional content, reuse and adaptation of materials, and flexibility for
 648 implementation in organized courses or by self-paced learners. Although it is relatively new, several
 649 cases observed enhanced learning of concepts and technical skills by students using HydroLearn and
 650 its precursors (Habib et al., 2019; Lane et al., 2021; Merck et al., 2021). Although it does not natively
 651 support launching and running notebooks, Lane et al. (2021) demonstrated linking notebooks via
 652 HydroShare.

653 **4.2.2 Online Module Development**

654 Based on the survey results, online educational materials are being used and modules have potential
 655 to address challenges in hydroinformatics and water data science education. However, there is
 656 substantial variety in topics and methods of instruction. While a unified curriculum and approach to
 657 the subject matter may be appealing, it does not match the reality of a rapidly changing field with
 658 dynamic courses and instructors. Instead, we sought to develop and publish example educational
 659 modules that focus on addressing gaps identified by participants and to illustrate an approach for
 660 additional online content creation and sharing.

661 The online modules were designed to address key challenges/gaps in hydroinformatics and water data
 662 science education reported by instructors. These gaps relate to: 1) content, 2) platform, and 3)
 663 organization. Regarding content, there is a lack of data-driven and problem-based learning that uses
 664 datasets from the water domain. Instructors requested notebooks for online coding examples, and
 665 there is a need for baseline levels of instruction in coding and scripting. To address the content gap,
 666 online educational content should include interactive code with water-related data and problems.
 667 Currently, instructors use various platforms for hosting educational content, and participants repeated
 668 the need for a system to facilitate upload, discovery, and community involvement. The platform gap
 669 may be addressed by publishing and publicizing resources in a system that meets many of the criteria
 670 in Table 4. We add that active and ongoing support are essential to ensure that the resources are not
 671 siloed or lost. Finally, the organization gap can be addressed by ensuring that the content is designed
 672 and structured to be modular and adaptable to different instructors, courses, and modes of delivery.

673 For our online modules, we worked to follow these recommendations to address the needs of
 674 hydroinformatics and water data science education. The modules address four topics: (1)
 675 Programmatically accessing water data via web services, (2) The sensor data life cycle and sensor
 676 data quality control, (3) Relational databases and SQL querying, and (4) Machine learning for
 677 classification (Table 5). These topics were selected based on survey and interview results indicating
 678 the need for reproducible code and the growing importance of high frequency sensor data, data
 679 quality control, databases, big data, web technologies, and machine learning. In conceptualizing these
 680 modules, we drew from our own expertise and datasets generated or used as part of our research
 681 efforts. The datasets are available for reuse, or instructors could apply the examples to data from
 682 other locations.

683 **4.2.3 Online Module Implementation**

684 HydroLearn facilitates a “Backward Design” approach wherein desired outcomes are first defined,
 685 then authentic tasks are crafted to meet outcomes, then instructional content is designed to present
 686 necessary information (Maggioni et al., 2020). Although in our case, development did not proceed in
 687 this order, the essential elements in our module design methodology correspond to backward design
 688 concepts and specific HydroLearn components: 1) learning objectives map to desired outcomes, 2)
 689 narrative maps to instructional content, 3) example code maps to both instructional content and

690 authentic tasks (i.e., learning activities in HydroLearn), and 4) technical assignment maps to
 691 authentic tasks (learning activities). Implementation of each of the components in HydroLearn is
 692 reported in the following subsections.

693 **4.2.3.1 Structure and Organization**

694 Each HydroLearn course contains “modules” or “sections”, which is the level to which we matched
 695 our modules. Although our modules stand alone, we included them under a single course umbrella
 696 (Hydroinformatics – USU 6110) to fit the HydroLearn schema. Modules consist of “subsections”
 697 comprised of “units”. The subsections are only titles, whereas content is contained as components
 698 (e.g., text, discussions, problems, HTML code, videos) within units. In HydroLearn, users have
 699 control over using either many components within fewer units, which makes interaction with content
 700 more vertical (i.e., scrolling on a single page), or using many units, which makes interaction with
 701 content more horizontal (i.e., navigating from unit to unit). While this provides flexibility in
 702 presenting content, we found that navigation between subsections and the different levels of each
 703 module was not always clear.

704 Figure 3 illustrates the organization of a module implemented in HydroLearn. While this is an
 705 intuitive structure, it imposes hierarchical levels that may be overly strict for some users. For
 706 example, we found “subsection” to be an unnecessary level for some modules and would have
 707 preferred to directly use “units” under the module level – or to have had control over the hierarchical
 708 levels. Granularity and organization are persistent questions for many repositories, regardless of
 709 content type (Horsburgh et al., 2016), and developers of many data repositories determined to leave
 710 organization and structure up to the user (e.g., FigShare, HydroShare, Zenodo). Although there are
 711 benefits to imposed structure, there is no single prescriptive pattern, and users may prefer different
 712 organizational levels. We identified degree of control as the main distinction between platforms, and
 713 giving users more control over organization and structure may improve the appeal and uptake of
 714 HydroLearn (and similar platforms). Despite these limitations, we were able to fit our module content
 715 to the HydroLearn structure.

716 **4.2.3.2 Learning Objectives**

717 Learning objectives are the desired outcomes of instruction and are ideally action-oriented, specific,
 718 and measurable. As a major part of its pedagogical emphasis (Lane et al., 2021), HydroLearn
 719 facilitates the creation of learning objectives, which can be entered manually or developed using a
 720 wizard according to an established structure (Maggioni et al., 2020). Although our learning
 721 objectives were defined prior to using HydroLearn, the wizard helped improve their specificity and
 722 robustness. HydroLearn functionality can directly connect module learning objectives to other
 723 module components (e.g., rubrics).

724 **4.2.3.3 Narrative**

725 For each module, the narrative was created in slides with text and images, then content was
 726 transferred to HydroLearn. Because study participants reported commonly using slides for lectures,
 727 the modules include linked slide deck files. Overall, we were successful in translating our content to
 728 HydroLearn components. Despite it being somewhat tedious to adapt text to HTML and to import
 729 and export images from slides to HydroLearn, we found it straightforward to edit content, to
 730 duplicate and modify components, to reorder units, and to publish changes. Building the course from
 731 the foundation of a HydroLearn template offered helpful organization and instructions.

732 **4.2.3.4 Example Code**

733 Each module contains 3-6 example scripts, each of which illustrates a task or piece of functionality
 734 (Table 5). There may be redundancy as examples build on each other, and instructors may choose to
 735 use fewer examples than provided. Code examples are shared in Jupyter notebooks as part of
 736 HydroShare resources that can be opened and run via the CUAHSI JupyterHub Server. We opted to
 737 use the CUAHSI JupyterHub because: 1) common Python packages are pre-installed, and additional
 738 packages can be installed by request, both of which are dependencies in our examples, and 2) data
 739 files can be called by code, which is essential for our modules. If data files are necessary to examples,
 740 they accompany the code notebooks in the HydroShare resources.

741 HydroShare resources containing notebooks and data can be linked and opened in a separate browser
 742 window or embedded as iFrames in HydroLearn units (Lane et al., 2021). We used links that directly
 743 launch the CUAHSI JupyterHub (Figure 3). From the link in HydroLearn, a user is prompted to sign
 744 into HydroShare and choose a coding environment and then is taken to their server directory where
 745 the notebooks are ready to be launched. This simplifies deployment of example code as learners do
 746 not have to install software or match a particular coding environment to view, execute, or manipulate
 747 code.

748 **4.2.3.5 Technical Assignment**

749 The technical assignments were conceptualized to meet recommendations in educational literature for
 750 open-ended, ill-defined, problem-based learning. For each assignment, students are expected to
 751 synthesize the narrative and code examples and apply the data and analysis tools to real-world
 752 applications. Each assignment requires coding and a written summary report to communicate and
 753 defend the results and conclusions. Within each module in HydroLearn, the assignment is a unit with
 754 components that specify the assigned tasks and expected deliverable. Assignments are accompanied
 755 by a customized rubric that sets expectations for students and facilitates objective grading for
 756 instructors. We adapted rubrics developed by a team of hydroinformatics instructors to each
 757 assignment (Burian et al., 2013). In another approach to assessment, HydroLearn offers rubric
 758 templates that connect the degree of student performance related to each learning objective (Lane et
 759 al., 2021).

760 **4.2.3.6 Platform Challenges and Opportunities**

761 We found that HydroLearn functionality supports needs as identified by study participants for online
 762 sharing and content organization. We also experienced challenges that present opportunities for
 763 continued advancement of educational platforms. In this section, we describe our experience using
 764 HydroLearn with respect to identified criteria, and each of the following paragraphs corresponds to a
 765 category in Table 4. While these outcomes may be specific to HydroLearn, we anticipate that other
 766 platforms face similar challenges and may require further development to support online educational
 767 resources.

768 Discoverability refers to locating content using keyword searches from Internet browsers and search
 769 functionality within a platform. After creating a course on HydroLearn, it appeared in the results of
 770 basic Internet searches. Within HydroLearn, we were able to search for the course and within the
 771 course. The platform could enhance discoverability by including keywords as part of the metadata for
 772 each course or module and filtering courses on keywords.

773 Metadata are displayed on the course landing page. The course template suggests metadata elements,
 774 which we used (e.g., target audience, tools needed, suggested citation), but elements are optional.

775 HydroLearn could better standardize metadata by requiring certain elements and by automatically
776 generating elements where possible. Creating metadata requires editing HTML code, and
777 HydroLearn could improve usability through webforms or markdown.

778 Navigability of HydroLearn courses is dictated by the hierarchical structure described in Section
779 4.2.3.1. Even with a logical organization for content, moving between sections and knowing how to
780 proceed through the module sequentially can be challenging for beginners. This may be improved by
781 adding text to the icons in the navigation bar and by displaying a course outline and navigation in a
782 persistent sidebar.

783 In Table 4, content refers to the types of files that are supported by the platform. We were able to use
784 HydroLearn to share text, images, interactive websites, and to link files for download. Videos,
785 equations, code snippets, and other HTML components are also supported. Supporting either a
786 JupyterHub for launching notebooks or more directly integrating with the CUAHSI JupyterHub
787 would strengthen the platform's ability to support code files.

788 Separate access for students and instructors is supported by HydroLearn. Course creators can elect to
789 restrict access of certain content to course staff. Other instructors can access restricted content by
790 exporting the course or by contacting course creators, though that may be unreliable. Although we
791 used open-ended assignments, some require specific coding tasks. In these cases, we created scripts
792 or notebooks as a solution key to the assignment, and we were able to use this functionality to restrict
793 access without separating the solution from course materials.

794 Licenses can be specified by creators at the course level. HydroLearn supports Creative Commons
795 licenses (e.g., Attribution, Noncommercial, No Derivatives, Share Alike), and related icons and
796 messaging are displayed on course subsection pages. Licensing could be made clearer if displayed
797 prominently on the course landing page.

798 Scalability refers to the ability for multiple users (e.g., classes of students) to use the materials or
799 program. We have not yet tested HydroLearn in the context of multiple simultaneous users, but we
800 are not aware of any limitations. It is built on an established online learning platform (edX), which
801 offers robustness. There may be scaling issues with many users running notebooks on the CUAHSI
802 JupyterHub, for which Lane et al. (2021) observed student frustration related to losing server
803 connection and authentication.

804 Reusability of educational materials is an intent of HydroLearn, and modules are expected to be
805 designed with consideration for uptake by other instructors. While the modules described here have
806 not yet been reused, we found it straightforward to export and customize a HydroLearn course, and
807 Lane et al. (2021) report that adaptation of a HydroLearn course by instructors at other institutions
808 was straightforward. Reusability is facilitated by licenses and citations, and the course metadata
809 template includes "Adapted From" to acknowledge source material. HydroLearn courses have been
810 used for both online and in-person instruction and can be designed to be student-paced or with an
811 imposed schedule making them compatible to the mix of modalities reported by study participants.

812 Citations are a recommended (but optional) metadata element for HydroLearn courses. Creators can
813 structure the citation as desired, and it is displayed on the course landing page. There is opportunity
814 for the platform to standardize by automatically generating a citation for each course or module, as is
815 done for data and code resources in HydroShare (Horsburgh et al., 2016).

816 Curation of courses is not required in HydroLearn, and instructors may deposit and share content
 817 without review. However, most of the modules currently available on HydroLearn were developed
 818 through intensive summer hackathons including substantive instruction on pedagogical best practices
 819 and feedback from the HydroLearn team (Maggioni et al., 2020; Gallagher et al *in prep*). As a result,
 820 much of the educational content shared on HydroLearn meets their criteria for high quality modules.
 821 However, there is no long-term system in place for module review and curation by the project team.
 822 As our modules were developed outside of the formal hackathons, we requested the feedback of a
 823 HydroLearn team member who was able to review and offer helpful suggestions. The approach of
 824 offering but not requiring curation balances increased overhead with fostering high quality content.
 825 Also, compensating fellows increases their motivation to deposit high quality material, as noted by
 826 study participants.

827 Educational support refers to assistance with teaching pedagogy and tasks, and is provided by
 828 HydroLearn through multiple features. HydroLearn emphasizes learning objectives throughout
 829 course development and includes functionality for various problem types to assess student learning
 830 (e.g., multiple choice questions, open responses, advanced mathematical expressions). Following
 831 templates and recommendations, capitalizing on features, and taking advantage of review by
 832 HydroLearn staff offers an approach that will result in a robust pedagogy. Although we did not tap
 833 into all these capabilities in developing modules, this is a major benefit of HydroLearn.

834 Collaboration is facilitated in HydroLearn through the inclusion of multiple instructors who share
 835 editing abilities and co-authorship on a course. HydroLearn also has the ability give feedback
 836 through comments. It was uncomplicated to add instructors to our course and for all authors to edit
 837 materials; however, we did not experiment with feedback.

838 **4.3 Outlook for the Future of Hydroinformatics and Water Data Science Instruction**

839 In light of the transition to online courses precipitated by the COVID-19 pandemic as well as the
 840 growing prevalence of material online, instructors may need to consider how to best bring value to
 841 their course offerings. As expressed by one interview participant:

842 *“...the incentive, the value proposition of the classroom is fundamentally altered after COVID.*
 843 *...No matter how good somebody is at explaining something, there's always somebody better*
 844 *on the internet. ...what really is the role of the instructor...and modern classroom? ...*
 845 *Obviously in person, it's made easier by the fact that [students are] there. But then the question*
 846 *is, is it you or is it the fact that they can be around each other? ...online [content] is growing*
 847 *and dismissing it [is naïve].”*

848 Several participants indicated that the merit of an organized course for students is interaction with an
 849 instructor curating content and facilitating learning. Despite the possibility of learning from purely
 850 online materials, a knowledgeable and engaged instructor still has much to offer.

851 *“...engagement, pre and post class discussions, office hours, a tailored curriculum to the*
 852 *class. ...my class changes every semester based on...what I'm perceiving in lecture and what*
 853 *I'm hearing in office hours.”*

854 *“We're in an era where it's not necessarily the content that's most valuable to the students, it's*
 855 *me facilitating their use of the content. And so, I think that the content should be shared as*
 856 *broadly as possible.”*

857 Access to educational material that is current, flexible, and reusable can help instructors adapt to the
858 rapidly evolving field. The modules presented in this work are a first step and an invitation to the
859 community to continue development and sharing of content online. In this way, instructors can
860 address the gaps we identified related to content, platform, and organization of community materials.
861 As instructors consult the list of topics of growing importance in the field and consider which of their
862 materials and datasets may be most useful as community resources, we envision that they will deposit
863 modules that include relevant water-related datasets and accessible code examples with ideas for
864 problem-based learning.

865 This work illustrated that materials deposited in HydroLearn are modular and adaptable, and as
866 HydroLearn advances and usage increases, it may address the platform gap related to limited
867 community and siloed resources. This vision depends not only on sharing content, but also on uptake
868 by other instructors implementing, reviewing, and engaging with shared material. As articulated by
869 study participants, reciprocity, credit, and feedback will all motivate sharing and reuse of content,
870 which will help advance instruction in hydroinformatics and water data science.

871 **5 Conclusion**

872 We interviewed and surveyed instructors that teach hydroinformatics and water data science at
873 collegiate and professional levels to assess the current state of practice regarding topics, teaching
874 tools, shifts to online instruction related to COVID-19, and the potential for shared online resources.
875 Results indicated a mix of online and in-person modalities. Although nearly all courses moved online
876 because of COVID-19, there was a strong preference for in-person learning, and most were returning
877 to in-person teaching. However, instructors are retaining some virtual aspects that facilitated
878 instruction, particularly related to live coding. Student feedback and interaction were lacking in
879 purely online modalities, leading to the conclusion that even successful online resources and tools
880 require deliberate interpersonal components.

881 Instructors generally customized teaching materials to meet the demands of a rapidly developing
882 field. Results show variety in topics currently taught and topics of growing importance, with
883 consensus around emphasizing reproducible code development in open-source languages and
884 competence regarding learning and selecting informatics tools. Live coding for online and in-person
885 settings was facilitated by the growing use of online code notebooks. A key finding was a common
886 need for technical skill development earlier in students' college experience.

887 We found high interest in shared online educational content, although a lack of recognition,
888 reciprocity, community, and credit were deterrents to sharing. Although participants currently use
889 multiple layers of miscellaneous educational platforms, there was an expressed need for common
890 community resources. Participants reported gaps and challenges to hydroinformatics instruction
891 related to content (water-related datasets, online notebooks, and data-driven problems), platform
892 (community-based, facilitates discovery), and organization (modular, adaptable).

893 The educational modules we developed attempt to address these challenges, center around subjects of
894 growing importance in the field, and were developed and deposited in HydroLearn, a platform for
895 water-related educational modules. We found that HydroLearn was successful in meeting
896 participants' criteria for a community content platform. HydroLearn has robust functionality for
897 educational tools and pedagogy, and its scaffolding supports content sharing (i.e., metadata, citation,
898 discoverability, collaboration, reusability). The major drawbacks were related to an imposed
899 hierarchical structure, and improvements could be made regarding minimum metadata requirements.

900 These modules are a step toward developing a rich set of online resources and an active community
901 of instructors to meet the advancements in hydroinformatics and water data science.

902 In conclusion, shared online resources hold promise for overcoming challenges in hydroinformatics
903 and water data science education. As instructors are already accustomed to tailoring content for their
904 courses, adapting online modules with a water emphasis is accessible. Current and flexible resources
905 would help instructors keep pace with the rapid development of technology and topics in the field
906 and maintain the value of their course and teaching for students.

907 **6 Author Contributions**

908 ASJ, JSH, and BAL conceptualized the presentation of survey and interview results with associated
909 educational modules. ASJ formulated the survey and interview design with support from JSH and
910 CGF. ASJ facilitated all surveys and interviews and analyzed the responses. ASJ, JSH, and CJPB
911 created the educational modules and published them with support from BAL. ASJ wrote the
912 manuscript with consultation and contributions from JSH, CGF, BAL, and CJPB.

913 **7 Funding**

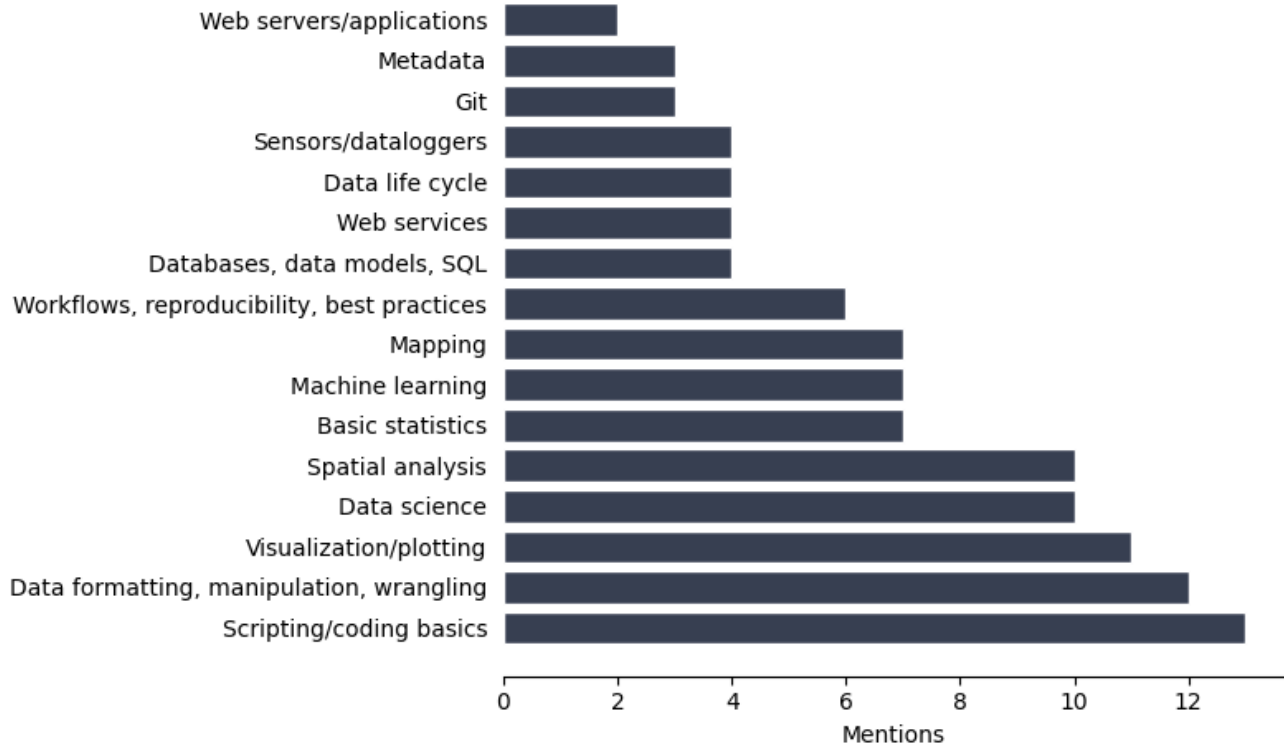

914 This research was primarily funded by the United States National Science Foundation under grant
915 number 1931297. Additional support for the educational/training modules was provided by the FAIR
916 Cyber Training Fellowship program at Purdue University corresponding to National Science
917 Foundation grant number 1829764. Any opinions, findings, and conclusions or recommendations
918 expressed are those of the authors and do not necessarily reflect the views of the National Science
919 Foundation. Additional funding support was provided by the Utah Water Research Laboratory at
920 Utah State University.

921 **8 Acknowledgments**

922 We gratefully acknowledge the input and expertise of the instructors who were participants in the
923 surveys and interviews reported in this paper.

924 **9 Data Availability Statement**

925 The materials generated by and reported by this work are publicly available. The survey responses
926 and interview transcripts are available via HydroShare (Jones et al., 2021). The educational modules
927 are published via HydroLearn (Jones, A.S. et al., 2022) along with code and associated datasets in
928 HydroShare (Jones et al., 2022).

929

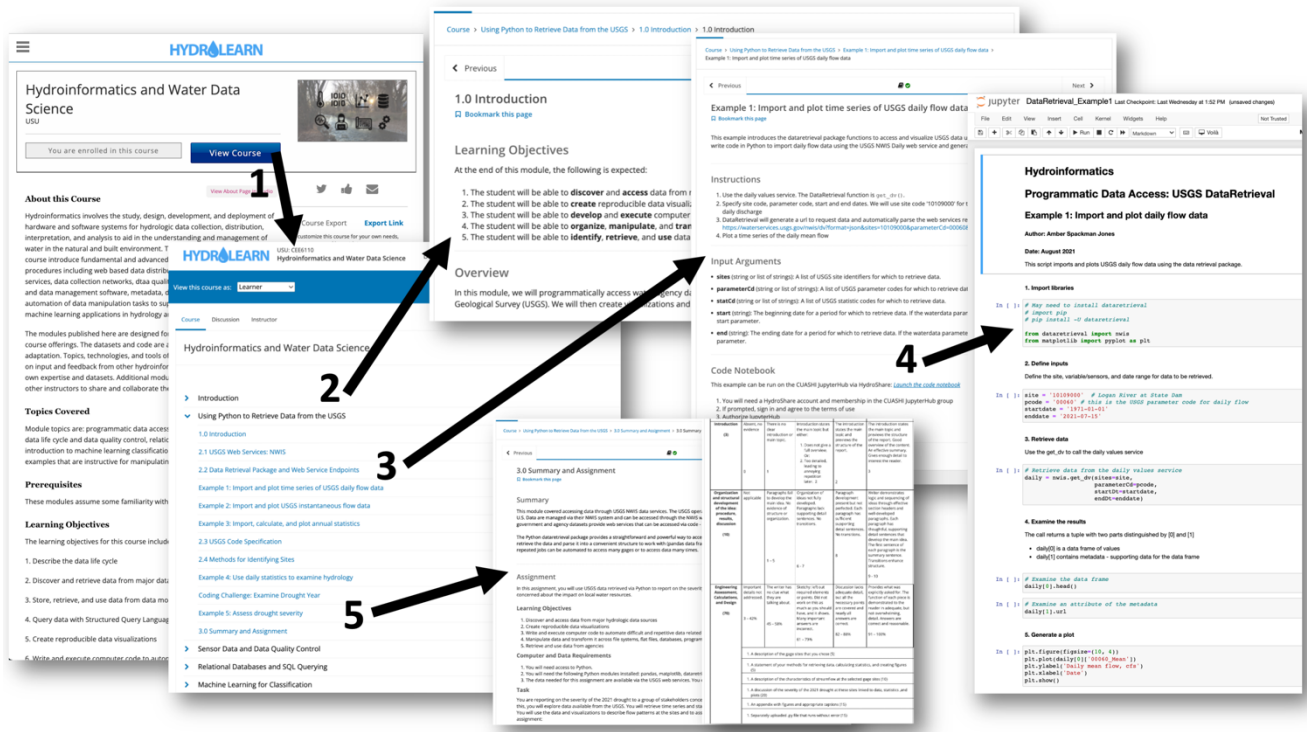

930 Figure 1. Count of mentions related to subjects taught by participants.

931

932 Figure 2. Count of mentions related to subjects of growing importance sorted by thematic topics.

933

934

935 Figure 3. Module implementation in HydroLearn. The numbered steps indicate the order of workflow
 936 and the location of essential module elements: 1) the course landing page contains metadata and links
 937 to a course outline, 2) learning objectives in the module introduction, 3) the narrative consists of text,
 938 links, images, tables, and code snippets, 4) code examples are interactive notebooks in the CUAHSI
 939 JupyterHub linked from HydroLearn, and 5) the technical assignment and associated rubric are a
 940 separate module component.

941 Table 1. Survey/interview questions

Survey/Interview Questions
The term "hydroinformatics" is used throughout. If your course or program uses a different title or term (e.g., "water data science"), consider that term instead.
Course Details
What is the name of the hydroinformatics-related course/program at your institution?
Is this course/program taught at a graduate level?
Are any hydroinformatics topics taught at an undergraduate level?
How is "hydroinformatics" defined in the context of the course/program offered at your institution?
What are the objectives for the hydroinformatics related course/courses/or programs offered at your institution?
Course Expectations
What prerequisite informatics skills are expected of students?
Do most students exhibit the prerequisite informatics skills at the start of the course?
What informatics skills (and level of skill) are students expected to attain in this course?
What benefits have students derived from taking the course? This could be quantitative or anecdotal.
Formats
What are the sources of the teaching materials used for the course/program?
What is the course/program format? (e.g., in-person, online, etc.) Please clarify if this changed due to COVID.
What platforms or instructional tools are being used in course delivery? (e.g., Canvas, HydroLearn, MyGeoHub, HydroShare, etc.) Please clarify if this changed due to COVID.
Did the COVID pandemic impact instruction related to hydroinformatics courses at your institution? If so, how?
What platforms or instructional tools have proven effective for in person versus online instruction (if your course has been offered online)?
If your courses have been offered online (due to covid or other reasons), what were the biggest challenges in delivering online instruction?
Topics and Technologies
What topics are emphasized in the hydroinformatics courses at your institution? (e.g., machine learning, databases and data models, numerical modeling)
What informatics technologies are emphasized? (e.g., Python, R, MySQL, ArcGIS)
What (if any) geospatial data and techniques are covered in the hydroinformatics course(s) at your institution?
How have the topics and technologies changed over the time that the course(s) have been taught?
What topics and technologies are growing in importance in hydroinformatics?
What are the gaps in existing hydroinformatics instruction/education?
Shared Resources
What types of shared community resources for instruction would be useful? (e.g., online modules that could be incorporated into courses)
In developing shared resources, what topics would be helpful in addressing gaps and challenges?
What formats would be conducive to shared resources?
What informatics technologies would be useful for shared resources?
What is your level of interest in sharing and exchanging teaching resources and materials with the community? (Very Interested, Interested, Moderately Interested, Slightly Interested, Not Interested)
What would motivate hydroinformatics instructors to participate in sharing/exchanging teaching resources?
In your view, what resources would a useful shared educational module consist of?
Wrap Up
Do you know of any other instructors who would be a good fit for this survey/interview? Please provide a name, institution, and email address (if known).

942

943 Table 2. Courses taught by study participants.

Course Titles	Count	Audience
Hydroinformatics	5	Graduate (4), Undergraduate and Graduate (1)
Informatics for Sustainable Systems	1	Graduate
Physical Hydrology (with a Hydroinformatics Unit)	1	Undergraduate and Graduate
Intro to Environmental Data Science	1	Graduate
Water Resource Data Science Applications	1	Graduate
Earth Resources Data Science	1	Graduate
Ecological and Environmental Data and Tools	1	Graduate
Introduction to Data Science	2	Undergraduate and Professional
R for Water Resources Data Science	1	Professional
R for Water Resources Research	1	Undergraduate and Graduate
Python for Environmental Research	1	Graduate
Research Computing in Earth and Environmental Sciences	1	Graduate
Modeling Earth and Environmental Systems	1	Graduate
Computational Watershed Hydrology	1	Undergraduate and Graduate
Data Analysis for Water Quality Management	1	Graduate
Sensing and Data	1	Graduate

944

945 Table 3. Educational platforms and instances of hydroinformatics or related implementations.

Platform	Description	Examples
HydroLearn https://www.hydrolearn.org/	Specifically designed for instructors to post and share educational modules for hydrology and water resources	(Bandaragoda and Wen, 2020)
MyGeoHub https://mygeohub.org/courses	Hosts groups, datasets, tools, and educational content for geoscience research and education	(Hamilton, 2021)
environmental data-driven inquiry and exploration (eddie) https://serc.carleton.edu/eddie/index.html	Repository for classroom modules and datasets for environmental subjects	No hydroinformatics or water data science modules. Stream Discharge Module: (Bader et al., 2015)
Excellence in Systems Analysis Teaching and Innovative Communication (ECSTATIC) https://digitalcommons.usu.edu/ecstatic/	Repository for water resources systems analysis teaching and communication materials	(Gorelick and Characklis, 2019)
HydroShare https://www.hydroshare.org/	Repository for sharing water related data, models, and code. HydroShare is generally focused on data and code, but several instructors have also used it for educational materials.	(Garousi-Nejad and Lane, 2021; Ward et al., 2021)
GitHub https://github.com/	Repository for software and code with version control	(Flores, 2021)
Personal or institutional website	Users determine structure	(Kerkez, 2019)
Canvas (or similar)	Institutional learning management system	(Horsburgh, 2019)
Customized books/websites	Users determine structure. Some programming languages have packages to convert code to an online book or website.	(Gannon, 2021; Peek and Pauloo, 2021)

946

Table 4. Characteristics of educational platforms related to instructor-defined criteria.

Platform	Discoverability	Metadata	Navigability	Content	Student/Instructor Access	Licenses	Scalability	Reusability	Citation	Curation	Education Support	Collaboration
HydroLearn	Searchable, indexed for Internet search	User-defined metadata	Hierarchical structure. Expandable navigation menu.	Text, videos, links to files and webpages	Supports separate access	Creative commons licenses	Not expected to be an issue	Expected	User-defined	Available but optional	Learning objectives, discussions, many problem types	Commenting and creating derivatives supported
MyGeoHub	Searchable, keywords, indexed for Internet search	Basic description	Courses with modules containing files	Any file type. Natively run Jupyter notebooks	Not explicit support, but could be achieved with groups	Creative commons licenses	Some issues reported for multiple users running notebooks	Unclear	Citation generated but not obvious on landing page	Approval required for uploading files	Quizzes, exama, homework, discussions	Participants may comment
eddie	Searchable, filterable, indexed for Internet search	Detailed outline	Outline with links to files	Any file type	Supports separate access	Unclear	Unclear	Expected	Unclear	Multistep review process	Structured around teaching objective	Unclear
ECSTATIC	Searchable, filterable by type	Abstract and keywords	All content in zip file	Any file type	No	Present on landing page	NA	Expected	Included	Very light review	None	None
HydroShare	Searchable, filterable, indexed for Internet search	Abstract and keywords		Any file type. Natively run Jupyter notebooks with data files.	Could be achieved using different privacy levels	Present on landing page	Could occur if there are many users on the Jupyter Hub server	Expected	Included	None	None	Commenting and groups
GitHub	Searchable, but difficult	Minimal metadata required	Creators can structure files as desired	Any file type. Code and markdown rendered.	Could be achieved using different privacy levels	Available but not required	No issues	Expected	Can be generated	None	None	Facilitated by forking another repository
Personal website, Canvas, Custom books	Only if user knows what to look for	Creators can include as much as desired	Creators can structure files as desired	Any file type	Separate access for creator, but not for reuse	Possibly	NA	Unclear	Possibly	None	None	None

949 Table 5. Educational modules developed and deployed as part of this work with descriptions of
 950 essential components and datasets. Modules are accessed at Jones, A.S. et al., (2022).

Module	Programmatic data access	Sensor data quality control	Databases and SQL	Machine learning classification
Topics	<ul style="list-style-type: none"> • Open web technology • High frequency data • Visualization • Big data 	<ul style="list-style-type: none"> • High frequency data • Data quality • Big data • Machine learning 	<ul style="list-style-type: none"> • Databases and SQL • High frequency data • Big data 	<ul style="list-style-type: none"> • Machine learning • Smart sensors • High frequency data
Narrative	<ul style="list-style-type: none"> • The United States Geological Survey (USGS) National Water Information System (NWIS) • Web services for accessing data 	<ul style="list-style-type: none"> • Data life cycle for <i>in situ</i> aquatic sensor data • Sensors, hardware, and infrastructure • Sensor data quality assurance and quality control 	<ul style="list-style-type: none"> • Data models and database implementation • SQL queries (e.g., selecting, joining, and aggregating data) • Observations Data Model (ODM, Horsburgh et al., 2008) 	<ul style="list-style-type: none"> • Common machine learning approaches, concepts, and algorithms • Python package scikit-learn Problem of labeling residential water end use event data
Code Examples	<ul style="list-style-type: none"> • Use the Python dataretrieval package • Import and plot data via USGS NWIS web service endpoints • Examine local hydrology using flow statistics 	<ul style="list-style-type: none"> • Import and plot a time series • Use the Python pyhydroqc package • Perform rules-based and model-based anomaly detection 	<ul style="list-style-type: none"> • Use SQL to select data, sort results, perform joins between tables, aggregate and group data 	<ul style="list-style-type: none"> • Explore data features • Apply basic machine learning model • Compare multiple algorithms • Hyperparameter tuning and optimization
Assignment	Retrieve data, calculate statistics, and generate plots to explain the impact and severity of drought conditions	Apply package algorithms and determine performance metrics to consider using the software in an observatory quality control workflow	Construct SQL queries to compare data to state water quality criteria and identify potential water temperature impairment	Apply machine learning models to develop guidance for using smart meters to collect residential water use data
Dataset	Water data collected by national agency available via web. Similar data/methods may be available for data from other agencies.	Flat files in containing high frequency Logan River aquatic data with raw data and technician labels. Posted on HydroShare.	SQLite ODM database with high frequency water temperature data for several sites in the Logan River. Posted on HydroShare.	Flat file of labeled residential water use event data. Posted on HydroShare.
