8

9 **Abstract:**

10 A mangrove ecosystem restoration project was carried for 3 years in the Mauritanian side of  
11 the River Senegal Delta where scarce scientific and/or technical references exist on these  
12 mangroves located in the northernmost limit on the West African coast. The construction of the  
13 Manantali and the Diama dams transformed the once exuberant delta to an artificial estuary  
14 and had dramatically affected the inland mangrove ecosystems. Thousands of mangrove  
15 seedlings were grown annually in the PND and community nurseries. A participatory approach  
16 was adopted for mangrove plantings where chicken and goat manure was used as biological  
17 fertilizer. Finally, 42.000 mangrove trees were planted in 4 sites located in the area of the Park.  
18 Two years after planting, the mangrove trees reached a height of about 2 m, and constitute  
19 already a source of forage for herds of camels and goats. Success of such project in a fragile  
20 and desert environment could set the way for future mangrove restoration projects in Mauritania  
21 or other less hostile areas.

22

23 **Introduction:**

24 Mangrove ecosystems are heterogeneous habitats with an unusual variety of animals  
25 and plants adapted to the environmental conditions of highly saline, frequently inundated, soft  
26 bottomed anaerobic mud (Macintosh and Ashton, 2002). Most commonly, they are found on  
27 the tropics and sub-tropics, on riverbanks and along coastlines subjected to tidal influences,  
28 being unusually adapted to anaerobic conditions of both salt and freshwater environments; and  
29 to muddy, shifting saline conditions (Auriol et al., 2010). Extensive research has been carried  
30 out on the ecology, structure and functioning of mangrove ecosystems. However, the findings

31 have not been interpreted in a management framework, thus mangrove forests around the world  
32 continue to be over-exploited, converted to aquaculture ponds, and polluted (Kairo et al., 2001).  
33 While mangrove planting and management has a long history in Southeast Asia (Watson, 1928),  
34 and West Africa (Grewe, 1941; Chapman, 1977), information on earlier mangrove plantation  
35 practices in East Africa is scanty (Kairo et al., 2001; Semesi, 1998). Furthermore, very scarce  
36 scientific literature can be found on the Mauritanian mangrove ecosystems (Dahdouh-Guebas  
37 and Koedam, 2001; Auriol et al., 2010).

38 Novel approaches to mangrove planting in desert countries have been published (Sato  
39 et al., 2005; Sato et al., 2011). They prove establishing mangrove trees in salty coastal lands is  
40 possible providing an appropriate mineral nutrition i.e. nitrogen, phosphorus and iron. Around  
41 a million trees have been planted on the Red Sea coast of Eritrea (Sato et al., 2005). Such forests  
42 could provide forage for goats and serve as nurseries for fish reproduction. These important  
43 findings deserve to be considered for future mangrove plantings and/or mangrove restoration  
44 projects in Africa's desert countries.

45 Mangrove ecosystems at Diawling National Park are biogeographically marginal and  
46 have received little attention. These fragile ecosystems' overexploitation for firewood and for  
47 boat construction combined with reduced floods caused by dams 'construction and the Sahelian  
48 drought have furthermore tremendously increased pressure on these ecosystems by herds of  
49 grazing camels and goats. Indeed, infrastructure development, tourism-based disturbance,  
50 agricultural development impacts, and habitat loss threatens mangrove ecosystems  
51 establishment and its further development. Following the extinction of entire mangrove forest  
52 patches from the DNP area (picture 1) and its subsequent dramatic effects both environmentally  
53 and economically on locals, the need for restoring the mangrove ecosystem was early  
54 documented by some authors (Gonzalez, 2005) and indeed advocated by villagers neighboring  
55 the Senegal River Delta.

56 Consequently, restoring degraded mangrove ecosystems and establishing sustainable  
57 management schemes, especially for those located at the Diawling National Park, is fully  
58 justified both environmentally and economically. Since very few successful mangrove  
59 reforestations have been reported in arid coastal areas (Toledo et al., 2001), we hereby  
60 investigate a mangrove restoration project in an extreme environment as can be the Mauritanian  
61 desert. Past and present situations of the Senegal River Delta will be analyzed in reference to  
62 the existing mangrove ecosystems inland. Also, the methodology and progress of this mangrove

63 ecosystem restoration project will be detailed, and recommendations for similar future projects  
64 in desert countries will also be given.

65

## 66 **Materials and methods**

67 A project for mangrove ecosystem restoration at DNP, Mauritania has been launched by  
68 UNESCO-Rabat Office in Morocco since 2009 and lasted for a period of 3 years. In total, 4  
69 sites located in DNP were selected for this purpose: Gahra, Birette, Dar Essalam, and Dar  
70 Errahma, covering an area of 20 ha. In this paper, only mangrove restoration at Gahra and  
71 Birette sites will be treated.

72

### 73 **A/ Presentation of Diawling National Park (DNP).**

74 The DNP is located on the south-west of Mauritania and extends along the northern side of the  
75 Senegal River Delta (16°22'N, 16°23W) (Map 1). Initially a protected area in the 1980's, the  
76 park was created in January 1991 and was later designated by UNESCO as a Ramsar site in  
77 1994. It covers an area of 16.000 ha, and comprises a wide variety of landscapes ranging from  
78 islands, tidal mudflats, marshes and mangrove swamps, coastal sand dunes, *Acacia*  
79 *Senegalensis* forests...etc. The geographical location of villages within DNP witnesses the rich  
80 historic diversity of the delta settlers and paved the way for the actual social peace reigning in  
81 the park area (Gonzalez, 2005).

82 In the case of the DNP, a range of anthropogenic and natural factors have contributed to the  
83 large degradation of the mangrove ecosystems. According to Gonzalez (2005) these factors  
84 include i/ cuttings for timber, fuel, and charcoal ii/ over-grazing of mangroves by herds of  
85 camels and goats. However, the main reasons stem from the following:

86 i/ The Senegal river has two large dams along its course, the multi-purpose Manantali Dam in  
87 Mali and the Diama Dam just upstream of the delta for preventing access of salt water.  
88 Construction of Diama dam, in service from 1986, followed by the enclosure of the reservoir  
89 by embankments in 1990 completely disrupted the normal tide hydrology, cutting off water  
90 from large areas of the delta. The mangrove forest that once covered almost all the flood plains  
91 of DNP (Diawara, 1995), turned to scattered linear bands of mangrove trees matching

92

93

94 the contours of the tidal channels (Map 1). In other places, the lack of water and inorganic  
95 nutrients brought annually by the flood water resulted in large dry and infertile plains (picture  
96 1). The situation worsened with the Sahelian drought during the 1980's, and by the fact that the  
97 water in the Diama reservoir was regularly kept at its maximum level to reduce water pumping  
98 costs by local farmers (Hamerlynck and Duvail, 2003). Very high spring tides then carried  
99 highly saline waters across parts of the wetlands, causing widespread losses of mangroves and  
100 grasslands, with devastating impacts upon local fishing communities (Spalding et al., 2010).  
101 The green and productive mudflats turned dry and the Harmattan wind was blowing dust from  
102 the bare dry soil surface (Hamerlynck and Duvail, 2003).

103 **ii/** Finally, the huge hydrologic changes operated across time on the delta have turned the so-  
104 called pseudo-delta, by opposition to 'active' deltas having a number of distributaries (Duvail,  
105 2001), to the present more like artificial estuary (Hamerlynck and Duvail, 2003).

106

## 107 **B/ Description of mangrove ecosystems at DNP.**

108 It is generally accepted that only three of the eight mangrove species existing in West Africa  
109 are present in DNP: *Rhizophora racemosa*, *Avicennia germinans*, and possibly very few  
110 specimens of *Conocarpus erectus* in association with *Avicennia* stands (Gonzales, 2005).  
111 However, it is worth to note that during our surveys together with the DNP staff members, no  
112 *Conocarpus erectus* specimen were spotted anywhere on the Mauritanian side of the Senegal  
113 river Delta.

114 The fewer mangrove species found in the DNP are evidence of a biodiversity transition between  
115 two surrounding mangrove habitats: Sine Saloum in Senegal where pristine mangrove  
116 ecosystems exist and comprise 6 mangrove species covering 58.300 ha (JICA, 2005); and Banc  
117 d'Arguin National Park in Mauritania where mangroves reach their northernmost distribution  
118 and are comprised exclusively of *Avicennia germinans* (Dahdouh-Guebas and Koedam, 2001).  
119 Hence, it is reported that lower mangrove productivity might be expected in Mauritania where  
120 the trees are stunted and at the northernmost limit of their range in West Africa (White, 1983).

121 Like Sine Saloum delta where pure mangrove forests of *Rhizophora* spp. are found at the river  
122 mouth and riverbanks while *Avicennia Africana* with a high salt resistance is found in inland  
123 areas (JICA, 2005), mangroves at DNP show a similar zonation pattern (Figure 1). *Rhizophora*  
124 develops predominantly along the Riverbanks and on the muddy banks of the Delta islands  
125 (M'boyo, Diaos) (Map 1, Picture 2B); while *Avicennia* develops backward of the *Rizophora*  
126 stands (Picture 2A).

127 The mangrove ecosystems at the PND cover an area of less than 1 km<sup>2</sup> and are composed of  
128 stunted trees not exceeding 2 m height. Most of the inland *Avicennia germinans* are in the  
129 Ntiallakh basin, essentially forming scattered linear bands matching the contours of the tidal  
130 channels (Map 1). Exceptionally, some few dispersed specimens (less than a hundred) thrive  
131 far from tidal channels in the year-most dry Bell basin (Picture 3A), and Hassi Baba sites (Map  
132 1, Picture 3B). These remnant trees from a past exuberant mangrove ecosystem witness both  
133 the huge hydrological system change after the construction of the Diama dam and the unusual  
134 capacity of mangroves to grow in dry spots out of water for a long period of the year. This  
135 recalls the fact that *Avicennia* are not hydrophilic but halotolerant trees (Imebert, 2002 cited  
136 by Tandia, 2011). In this context, our observations suggest that *Avicennia* is geographically  
137 constrained by the ability of propagules to germinate in less humid environments.

138 The DNP inland display lower natural regeneration potential associated with restricted fertility;  
139 relative to other West African mangroves, which makes them very fragile regressive  
140 ecosystems (Diawara, 1995). In fact, most of the trees in the Ntiallakh basin produce no  
141 propagules even though these are flowering profusely. Similar observations were reported by  
142 Dahdouh-Guebas and Koedam (2001) at Band d'Aguin National Park quoting Duke (1990)  
143 who hypothesized that plant species at their biogeographical limit display a decreased fertility.  
144 However, the situation is reversed on the muddy banks of the delta islands where mangrove  
145 trees produce propagules abundantly. A similar situation was also observed by Wang'ondou et  
146 al., (2010) in Kenya, who concluded that zonation may have had an influence in fruiting of  
147 *Avicennia marina* since sites that were frequently inundated (seaward) supported prolonged  
148 budding and fruiting relative to those that were less inundated (landward sites).

149 In view of the above limitations, Gonzalez (2005) recommended an active restoration of the  
150 mangrove system at the PND. There are several advantages of using artificial regeneration: the  
151 species composition and distribution can be controlled, genetically improved stocks could be

152 introduced, and pest infestation can be controlled (Field, 1998); provided simple and  
153 economically feasible reforestation techniques are adopted (Thorhaug, 1990).

154

#### 155 **C/ Propagule collection and nursery procedures.**

156 *Avicennia germinans* (L.) reproduces by producing propagules through the process of  
157 cryptovivipary, which requires a significant energy investment (alleman and Hester, 2011).  
158 Hereafter, the same term will be used to refer to *Avicennia* seeds to keep with an abundant  
159 literature on the subject. For this project, propagules were collected annually from the Delta  
160 islands (M'boyo, Diaos), when these were in-season. The latter extends from July to September.

161 Nursery installment and a preliminary irrigation of the pots were done before propagule  
162 collection, so that propagule planting is not delayed and takes place the following day. Planting  
163 is done by inserting a third of the propagule lower part into moist soil. Through this process,  
164 propagules must be kept moist to avoid any drying. Frequent daily irrigation of the nursery was  
165 adopted because an air and/or sun exposure of 24 hours is sufficient to kill the propagules  
166 (Dahdouh-Guebas and Koedam, 2001).

167 Sato et al., (2005) supplemented mangrove seedlings on the Eritrean coast with N, P, and Fe.  
168 By fertilizing saplings, they were able to grow nearly one million trees on the muddy coast of  
169 Eritrea. In this case, we opted for manure fertilization for the following 2 reasons i) as a  
170 protected area, the park administration was apprehensive of the use of industrial fertilizer ii/ the  
171 price of fertilizers in Mauritania was prohibitive for use of thousands of trees.

172

#### 173 **D/ Restored mangrove sites and planting approach.**

174 Both Gahra and Birette sites were chosen for mangrove restoration operations (Map 2) with a  
175 planting density of 2 x 3 m spacing. The two sites display different features:

- 176 - Gahra site is relatively isolated and therefore protected from animal grazing. Also, this  
177 site is subject to high water salinity levels, especially at summertime (Map 2). It is  
178 located along N'tiallakh basin and so is connected to both sea and river waters resulting  
179 into brackish to salty water at certain periods.

180 - Birette is located immediately downstream of Diama dam and on the fringe of the border  
181 post to Senegal and so is subjected to frequent grazing by passing herds of cows and  
182 goats. Water salinity is lower than at Gahra site (Map 2).

183 Regular meetings with locals were organized in the two nearby villages to discuss the  
184 opportunity of such a project and the environmental and economic benefits for local villagers.  
185 Our participatory approach for mangrove plantings proved somehow difficult to apply since we  
186 were in difficulty to gather the 70 workers required for the hard work such as digging holes and  
187 planting the 5.000 mangrove saplings within 3 days frame at most, since the local population  
188 was mostly composed of women and children. In fact, adult men had in their majority  
189 immigrated to nearby capitals (Dakar and Nouakchott) for work.

190 Fencing was adopted for all mangrove restored sites to avoid predation by animals (camels,  
191 cows, and goats) since young saplings seemed more palatable to the animals than adult trees;  
192 an observation also reported by Gonzales (2005). However, Fencing was successful at Gahra  
193 but failed at Birette which is frequently subjected to grazing by passing herds of cows and goats.  
194 Finally, the fence rusted, and frequent breakouts were observed (Picture 4).

195

## 196 **Results and discussion**

### 197 **A/ Seedling growth at nursery**

198 During the first two years of the project, mangrove seedlings survivals in the nursery were 98  
199 and 93% respectively for the first and second year. Under optimal nursery management  
200 conditions (fertilization and irrigation), mangrove seedlings develop very well. In a period of 3  
201 months, seedlings had an average plant height of almost 1 m and approximately 8 leave pairs  
202 (Figure 2). Under adequate growth conditions, the rooting system which is extremely important  
203 for future development of the seedlings after planting in the field (picture 5), is well developed  
204 and roots maybe protruding from the pots.

205 Success of the present terrestrial nursery could provide an alternative to experimental nursery  
206 systems in a laboratory or flooded nurseries supplemented with NaCl (Wakushima et al., 1994)  
207 even though these were not transferred to the swamps for survival assessment.

208

209 **B/ Growth evaluation of restored areas.**

210 Two years after planting, a study was carried to assess overall situation at the two mangrove  
211 restored sites (Tandia, 2011). It focussed mainly on measuring tree height, tree diameter, and  
212 vegetation cover following a phyto-ecological transect in the two sites.

213 A number of *Avicennia* trees were sampled inside a 2.500 m<sup>2</sup> plot, at each of the two restored  
214 sites: 224 trees at Gahra and 102 at Birette. According to Tandia (2011), most tree heights  
215 ranged between ]1 – 1,5 m] and ]1,5 – 2 m]: 78 % and 88 % respectively at Gahra and Birette  
216 sites (Figure 3). Fewer trees exceeded 2 m height at Gahra restored site (6 %) but none at Birette.  
217 Overall, tree height evolution was similar within the 2 sites and averaged 1,34 m and 1,23 m  
218 respectively at Gahra and Birette after 2 years, which resulted in an annual increase of 0,67  
219 m/year and 0,61 m/year respectively comparable to values of 0,6 m/year and 0,51 m/year were  
220 reported by Louppe et al. (2008) in Ghana and Ndour et al. (2009) in Senegal respectively.

221 Considering tree diameter, it was reported that 71 % of trees at Gahra had diameters falling  
222 within ]0,5 – 1 m] while 80 % of those at Birette did not exceed 0,5 m diameter. According to  
223 the same author, tree diameter between the two restored sites were statistically different.  
224 Despite optimal salinity levels at Birette, trees diameter was significantly affected by grazing  
225 animals. In fact, Birette had never been tightly fenced and could not because of its location  
226 contiguous to border road. Under conditions of Gahra, only 2 % of trees could have diameters  
227 within ]1 – 3 m], showing most probably potential tree diameter that could be achieved under  
228 DNP conditions.

229

230 **C/ Monitoring of restored areas.**

231 Growth results above confirm the differences of vegetation cover between the two restored  
232 sites. Overall vegetation cover was higher at Gahra than at Birette for the reasons explained  
233 earlier (Figures 5A and 5B). Although, it's reported that water salinity levels play a key role in  
234 shaping *Avicennia* cover distribution along different sequences of a phyto-ecological transect  
235 (Tandia, 2011), we believe it's more about the hydrological conditions of each of the sequences.  
236 Accordingly, we think zonal distribution of *Avicennia* is dictated by the water depth at which  
237 underwater pneumatophores can thrive without the tree being asphyxiated, thing that  
238 *Rhizophora* can easily manage following the tide with it very long and tangled roots. Finally,

239 to our understanding, zonal distribution is not shaped by competition between the two species  
240 but more by optimal habitat for each of the species.

241 Yearly evolution of reforested sites is shown in pictures 6 and 7. Growth of the *Avicennia* trees  
242 was a success but animal predation remains among important factors to be considered. Trees  
243 were having abundant foliage, produced propagules and neighboring areas were harboring  
244 young saplings probably dispersed from the mother trees. Assuming this, we can conclude that  
245 our project has produced vector areas for mangrove propagules which will enhance natural  
246 regeneration along the N'tiallakh basin. Such results left us optimistic about the future of the  
247 mangrove ecosystem in the N'tiallakh basin. During the third and last year of the project, fences  
248 were rusting, and multiple breakouts were noticed from where goats and cows were accessing  
249 the restored areas. However, at this stage mangrove trees were sufficiently grown to thrive with  
250 grazing pressure from camels, goats...etc.

251

#### 252 **D/ Discussion.**

253 Two years after planting, *Avicennia* trees achieved optimal growth at Gahra and Birette sites:  
254 tree height averaged 1,34 m and 1,23 m; and most tree diameter fell within ]0,5 – 1 m] and ]0  
255 – 0,5 m] respectively. Growth differences between the two sites were due mostly to intense  
256 grazing by animals at Birette site. This site had never been tightly fenced and could not because  
257 of its location contiguous to border road. Salinity had no major effect on *Avicennia* trees growth.  
258 In fact, higher salinity levels were recorded at Gahra than Birette, however the former site  
259 displayed much better vegetation cover than the last one. Instead, grazing caused the main  
260 growth differences.

261 None of the reforested sites comprised *Rhizophora* specimen. However, *Avicennia* trees  
262 displayed the same zonal distribution as that of the pristine mangrove ecosystem on delta  
263 islands. This suggested that zonal distribution of *Avicennia* is dictated more by the water depth  
264 than by competition with *Rhizophora* stands.

265 One of the most important outputs of the present mangrove reforestation project was the fact  
266 that these areas provided a seedling stock for the entire basin. In fact, newly naturally  
267 regenerated areas were reported (Tandia, 2011) since propagules were abundant and spread  
268 following the tide to other bare and infertile areas.

269 **Conclusion and recommendations:**

270 The present experience is unique in Mauritania, but hopefully will draw more attention to  
271 conservation and further development of these ecosystems at their northernmost limit in the  
272 future. Like the Manzanar project in Eritrea which achieved planting nearly one million trees  
273 on the muddy coast, this project advocates for a “science for development” approach where  
274 simple observations and empirical methodology can lead to major breakthroughs in the field of  
275 greening highly deprived environments as deserts.

276 At the end of the present project, 42,000 mangrove trees have been planted at DNP. In the  
277 future, these forests will harbor numerous bird species, fish nurseries, and provide forage for  
278 local herds of camels, goats...etc. They will constitute in the future a source of wealth for the  
279 impoverished park population and remediate the negative effects of the hydrologic changes  
280 operated by construction of dams.

281 The community-based approach for restoring degraded ecosystems is foremost. Village’s  
282 youngsters did not witness the pristine state of mangrove ecosystems at DNP, and therefore  
283 feedback from older villagers were important to get them involved in rehabilitating their  
284 environment. One of the most important limitations to the project’s success was the extreme  
285 poverty and isolation of the park community. In fact, the population usually expects immediate  
286 benefits and is not willing to wait a few years for mangrove exploitation. In this sense, fencing  
287 reforested areas was capital to ensure proper development of the mangrove ecosystems.
